`analyzeChr` *Run the derfinder analysis on a chromosome*

Description

This is a major wrapper for running several key functions from this package. It is meant to be used after loadCoverage has been used for a specific chromosome. The steps run include makeModels, preprocessCoverage, calculateStats, calculatePvalues and annotating with annotateTranscripts and matchGenes.

Usage

```
analyzeChr(
  chr,
  coverageInfo,
  models,
  cutoffPre = 5,
  cutoffFstat = 1e-08,
  cutoffType = "theoretical",
  nPermute = 1,
```

```
  seeds = as.integer(gsub("-", "", Sys.Date())) + seq_len(nPermute),
  groupInfo,
  txdb = NULL,
  writeOutput = TRUE,
  runAnnotation = TRUE,
  lowMemDir = file.path(chr, "chunksDir"),
  smooth = FALSE,
  weights = NULL,
  smoothFunction = bumphunter::locfitByCluster,
  ...
)
```

Arguments

chr	Used for naming the output files when `writeOutput=TRUE` and the resulting `GRanges` object.
coverageInfo	A list containing a DataFrame –`$coverage`– with the coverage data and a logical Rle –`$position`– with the positions that passed the cutoff. This object is generated using loadCoverage. You should have specified a cutoff value for loadCoverage unless that you are using `colsubset` which will force a filtering step with filterData when running preprocessCoverage.
models	The output from makeModels.
cutoffPre	This argument is passed to preprocessCoverage (`cutoff`).
cutoffFstat	This is used to determine the cutoff argument of calculatePvalues and it's behaviour is determined by `cutoffType`.
cutoffType	If set to `empirical`, the `cutoffFstat` (example: 0.99) quantile is used via quantile. If set to `theoretical`, the theoretical `cutoffFstats` (example: 1e-08) is calculated via qf. If set to `manual`, `cutoffFstats` is passed to calculatePvalues without any other calculation.
nPermute	The number of permutations. Note that for a full chromosome, a small amount (10) of permutations is sufficient. If set to 0, no permutations are performed and thus no null regions are used, however, the `$regions` component is created.
seeds	An integer vector of length `nPermute` specifying the seeds to be used for each permutation. If `NULL` no seeds are used.
groupInfo	A factor specifying the group membership of each sample that can later be used with the plotting functions in the `derfinderPlot` package.
txdb	This argument is passed to annotateTranscripts. If `NULL`, TxDb.Hsapiens.UCSC.hg19.knownGene is used.
writeOutput	If `TRUE`, output Rdata files are created at each step inside a directory with the chromosome name (example: 'chr21' if `chrnum='21'`). One Rdata file is created for each component described in the return section.
runAnnotation	If `TRUE` annotateTranscripts and matchGenes are run. Otherwise these steps are skipped.
lowMemDir	If specified, each chunk is saved into a separate Rdata file under `lowMemDir` and later loaded in fstats.apply when running calculateStats and calculatePvalues. Using this option helps reduce the memory load as each fork in bplapply loads only the data needed for the chunk processing. The downside is a bit longer computation time due to input/output.

`smooth` Whether to smooth the F-statistics (`fstats`) or not. This is by default `FALSE`. For RNA-seq data we recommend using `FALSE`.

`weights` Weights used by the smoother as described in smoother.

`smoothFunction` A function to be used for smoothing the F-statistics. Two functions are provided by the `bumphunter` package: loessByCluster and runmedByCluster. If you are using your own custom function, it has to return a named list with an element called `$fitted` that contains the smoothed F-statistics and an element claled `$smoothed` that is a logical vector indicating whether the F-statistics were smoothed or not. If they are not smoothed, the original values will be used.

`...` Arguments passed to other methods and/or advanced arguments. Advanced arguments:

verbose If `TRUE` basic status updates will be printed along the way. Default `TRUE`.

scalefac This argument is passed to preprocessCoverage.

chunksize This argument is passed to preprocessCoverage.

returnOutput If `TRUE`, it returns a list with the results from each step. Otherwise, it returns `NULL`. Default: the opposite of `writeOutput`.

Passed to extendedMapSeqlevels, preprocessCoverage, calculateStats, calculatePvalues, annotateTranscripts, matchGenes, and define_cluster.

Details

If you are working with data from an organism different from 'Homo sapiens' specify so by setting the global 'species' and 'chrsStyle' options. For example: `options(species = 'arabidopsis_thaliana')` `options(chrsStyle = 'NCBI')`

Value

If `returnOutput=TRUE`, a list with six components:

timeinfo The wallclock timing information for each step.

optionsStats The main options used when running this function.

coveragePrep The output from preprocessCoverage.

fstats The output from calculateStats.

regions The output from calculatePvalues.

annotation The output from matchGenes.

These are the same components that are written to Rdata files if `writeOutput=TRUE`.

annotateRegions *Assign genomic states to regions*

Description

This function takes the regions found in calculatePvalues and assigns them genomic states contructed with makeGenomicState. The main workhorse functions are countOverlaps and findOverlaps.

Usage

```
annotateRegions(regions, genomicState, annotate = TRUE, ...)
```

Arguments

regions	The $regions output from calculatePvalues.
genomicState	A GRanges object created with makeGenomicState. It can be either the genomicState$fullGenome or genomicState$codingGenome component.
annotate	If TRUE then the regions are annotated by the genomic state. Otherwise, only the overlaps between the regions and the genomic states are computed.
...	Arguments passed to other methods and/or advanced arguments. Advanced arguments: **verbose** If TRUE basic status updates will be printed along the way. **ignore.strand** Passed on to findOverlaps-methods and countOverlaps. Default: TRUE. Passed to extendedMapSeqlevels, countOverlaps and findOverlaps-methods.

Details

You might want to specify arguments such as `minoverlap` to control how the overlaps are determined. See findOverlaps for further details.

Value

A list with elements `countTable` and `annotationList` (only if `annotate=TRUE`).

countTable This is a data.frame with the number of overlaps from the regions vs the genomic states with one type per column. For example, if `fullOrCoding='full'` then the columns are `exon`, `intergenic` and `intron`.

annotationList This is a `GRangesList` with the genomic states that overlapped with the regions. The names of this `GRangesList` correspond to the region index in `regions`.

makeGenomicState, calculatePvalues

Examples

```
## Annotate regions, first two only
annotatedRegions <- annotateRegions(
    regions = genomeRegions$regions[1:2],
    genomicState = genomicState$fullGenome, minoverlap = 1
)
annotatedRegions
```

`calculatePvalues` *Calculate p-values and identify regions*

Description

First, this function finds the regions of interest according to specified cutoffs. Then it permutes the samples and re-calculates the F-statistics. The area of the statistics from these segments are then used to calculate p-values for the original regions.

Usage

```
calculatePvalues(
  coveragePrep,
  models,
  fstats,
  nPermute = 1L,
  seeds = as.integer(gsub("-", "", Sys.Date())) + seq_len(nPermute),
  chr,
  cutoff = quantile(fstats, 0.99, na.rm = TRUE),
  significantCut = c(0.05, 0.1),
  lowMemDir = NULL,
```

```
  smooth = FALSE,
  weights = NULL,
  smoothFunction = bumphunter::locfitByCluster,
  ...
)
```

Arguments

coveragePrep	A list with $coverageProcessed, $mclapplyIndex, and $position normally generated using preprocessCoverage.
models	A list with $mod and $mod0 normally generated using makeModels.
fstats	A numerical Rle with the F-statistics normally generated using calculateStats.
nPermute	The number of permutations. Note that for a full chromosome, a small amount (10) of permutations is sufficient. If set to 0, no permutations are performed and thus no null regions are used, however, the $regions component is created.
seeds	An integer vector of length nPermute specifying the seeds to be used for each permutation. If NULL no seeds are used.
chr	A single element character vector specifying the chromosome name. This argument is passed to findRegions.
cutoff	F-statistic cutoff to use to determine segments.
significantCut	A vector of length two specifiying the cutoffs used to determine significance. The first element is used to determine significance for the P-values, while the second element is used for the Q-values (FDR adjusted P-values).
lowMemDir	The directory where the processed chunks are saved when using preprocessCoverage with a specified lowMemDir.
smooth	Whether to smooth the F-statistics (fstats) or not. This is by default FALSE. For RNA-seq data we recommend using FALSE.
weights	Weights used by the smoother as described in smoother.
smoothFunction	A function to be used for smoothing the F-statistics. Two functions are provided by the bumphunter package: loessByCluster and runmedByCluster. If you are using your own custom function, it has to return a named list with an element called $fitted that contains the smoothed F-statistics and an element claled $smoothed that is a logical vector indicating whether the F-statistics were smoothed or not. If they are not smoothed, the original values will be used.
...	Arguments passed to other methods and/or advanced arguments. Advanced arguments: **verbose** If TRUE basic status updates will be printed along the way. **scalefac** This argument is passed to fstats.apply and should be the same as the one used in preprocessCoverage. Default: 32. **method** Has to be either 'Matrix' (default), 'Rle' or 'regular'. See details in fstats.apply. **adjustF** A single value to adjust that is added in the denominator of the F-stat calculation. Useful when the Residual Sum of Squares of the alternative model is very small. Default: 0. **writeOutput** If TRUE then the regions are saved before calculating q-values, and then overwritten once the q-values are written. This argument was introduced to save the results from the permutations (can take some time) to investigate the problem described at https://support.bioconductor.org/p/62026/ **maxRegionGap** Passed to internal functions of findRegions. Default: 0. Passed to findRegions, smoothFunction and define_cluster.

Value

A list with four components:

regions is a GRanges with metadata columns given by findRegions with the additional metadata column `pvalues`: p-value of the region calculated via permutations of the samples; `qvalues`: the qvalues calculated using qvalue; `significant`: whether the p-value is less than 0.05 (by default); `significantQval`: whether the q-value is less than 0.10 (by default). It also includes the mean coverage of the region (mean from the mean coverage at each base calculated in preprocessCoverage). Furthermore, if `groupInfo` was not `NULL` in preprocessCoverage, then the group mean coverage is calculated as well as the log 2 fold change (using group 1 as the reference).

nullStats is a numeric Rle with the mean of the null statistics by segment.

nullWidths is a numeric Rle with the length of each of the segments in the null distribution. The area can be obtained by multiplying the absolute `nullstats` by the corresponding lengths.

nullPermutation is a Rle with the permutation number from which the null region originated from.

Examples

```
## Collapse the coverage information
collapsedFull <- collapseFullCoverage(list(genomeData$coverage),
    verbose = TRUE
)

## Calculate library size adjustments
sampleDepths <- sampleDepth(collapsedFull, probs = c(0.5), verbose = TRUE)

## Build the models
group <- genomeInfo$pop
adjustvars <- data.frame(genomeInfo$gender)
models <- makeModels(sampleDepths, testvars = group, adjustvars = adjustvars)

## Preprocess the data
## Automatic chunksize used to then compare 1 vs 4 cores in the 'do not run'
## section
prep <- preprocessCoverage(genomeData,
    groupInfo = group, cutoff = 0,
    scalefac = 32, chunksize = NULL, colsubset = NULL, mc.cores = 4
)

## Get the F statistics
fstats <- genomeFstats

## We recommend determining the cutoff to use based on the F-distribution
## although you could also based it on the observed F-statistics.

## In this example we use a low cutoff used for illustrative purposes
```

```
cutoff <- 1

## Calculate the p-values and define the regions of interest.
regsWithP <- calculatePvalues(prep, models, fstats,
    nPermute = 1, seeds = 1,
    chr = "chr21", cutoff = cutoff, mc.cores = 1, method = "regular"
)
regsWithP
## Not run:
## Calculate again, but with 10 permutations instead of just 1
regsWithP <- calculatePvalues(prep, models, fstats,
    nPermute = 10, seeds = 1:10,
    chr = "chr21", cutoff = cutoff, mc.cores = 2, method = "regular"
)

## Check that they are the same as the previously calculated regions
library(testthat)
expect_that(regsWithP, equals(genomeRegions))

## Histogram of the theoretical p-values by region
hist(pf(regsWithP$regions$value, df1 - df0, n - df1), main = "Distribution
    original p-values by region", freq = FALSE)

## Histogram of the permutted p-values by region
hist(regsWithP$regions$pvalues, main = "Distribution permutted p-values by
    region", freq = FALSE)

## MA style plot
library("ggplot2")
ma <- data.frame(
    mean = regsWithP$regions$meanCoverage,
    log2FoldChange = regsWithP$regions$log2FoldChangeYRIvsCEU
)
ggplot(ma, aes(x = log2(mean), y = log2FoldChange)) +
    geom_point() +
    ylab("Fold Change (log2)") +
    xlab("Mean coverage (log2)") +
    labs(title = "MA style plot")

## Annotate the results
library("bumphunter")
genes <- annotateTranscripts(TxDb.Hsapiens.UCSC.hg19.knownGene::TxDb.Hsapiens.UCSC.hg19.knownGene)
annotation <- matchGenes(regsWithP$regions, genes)
head(annotation)

## End(Not run)
```

`calculateStats` *Calculate F-statistics at base pair resolution from a loaded BAM files*

Description

After defining the models of interest (see makeModels) and pre-processing the data (see preprocessCoverage), use calculateStats to calculate the F-statistics at base-pair resolution.

Usage

```
calculateStats(coveragePrep, models, lowMemDir = NULL, ...)
```

Arguments

coveragePrep	A list with $coverageProcessed, $mclapplyIndex, and $position normally generated using preprocessCoverage.
models	A list with $mod and $mod0 normally generated using makeModels.
lowMemDir	The directory where the processed chunks are saved when using preprocessCoverage with a specified lowMemDir.
...	Arguments passed to other methods and/or advanced arguments. Advanced arguments: **verbose** If TRUE basic status updates will be printed along the way. **scalefac** This argument is passed to fstats.apply and should be the same as the one used in preprocessCoverage. Default: 32. **method** Has to be either 'Matrix' (default), 'Rle' or 'regular'. See details in fstats.apply. **adjustF** A single value to adjust that is added in the denominator of the F-stat calculation. Useful when the Residual Sum of Squares of the alternative model is very small. Default: 0. Passed to define_cluster.

Value

A numeric Rle with the F-statistics per base pair that passed the cutoff.

library("testthat")
expect_that(fstats, is_equivalent_to(genomeFstats))

## End(Not run)
```

`coerceGR` *Coerce the coverage to a GRanges object for a given sample*

Description

Given the output of fullCoverage, coerce the coverage to a GRanges object.

Usage

```
coerceGR(sample, fullCov, ...)
```

Arguments

`sample`	The name or integer index of the sample of interest to coerce to a `GRanges` object.
`fullCov`	A list where each element is the result from loadCoverage used with `returnCoverage = TRUE`. Can be generated using fullCoverage.
`...`	Arguments passed to other methods and/or advanced arguments. Advanced arguments: **verbose** If `TRUE` basic status updates will be printed along the way. **seqlengths** A named vector with the sequence lengths of the chromosomes. This argument is passed to GRanges. By default this is `NULL` and inferred from the data. Passed to define_cluster.

Value

A GRanges object with `score` metadata vector containing the coverage information for the specified sample. The ranges reported are only those for regions of the genome with coverage greater than zero.

Author(s)

Leonardo Collado-Torres

See Also

GRanges

Examples

```
## Create a small fullCov object with data only for chr21
fullCov <- list("chr21" = genomeDataRaw)

## Coerce to a GRanges the first sample
gr <- createBwSample("ERR009101",
    fullCov = fullCov,
    seqlengths = c("chr21" = 48129895)
)

## Explore the output
gr

## Coerces fullCoverage() output to GRanges for a given sample
```

`collapseFullCoverage` *Collapse full coverage information for efficient quantile computations*

Description

For a given data set this function collapses the full coverage information for each sample from all the chromosomes. The resulting information per sample is the number of bases with coverage 0, 1, etc. It is similar to using table() on a regular vector. This information is then used by sampleDepth for calculating the sample depth adjustments. The data set can loaded to R using (see fullCoverage) and optionally filtered using filterData.

Usage

```
collapseFullCoverage(fullCov, colsubset = NULL, save = FALSE, ...)
```

Arguments

`fullCov`	A list where each element is the result from loadCoverage used with `cutoff=NULL`. Can be generated using fullCoverage.
`colsubset`	Which columns of `coverageInfo$coverage` to use.
`save`	If `TRUE`, the result is saved as 'collapsedFull.Rdata'.
`...`	Arguments passed to other methods and/or advanced arguments. Advanced arguments: **verbose** If `TRUE` basic status updates will be printed along the way. Default: `FALSE`.

Value

A list with one element per sample. Then per sample, a list with two vector elements: `values` and `weights`. The first one is the coverage value and the second one is the number of bases with that value.

Author(s)

Leonardo Collado-Torres

See Also

fullCoverage, sampleDepth

Examples

```
## Collapse the coverage information for the filtered data
collapsedFull <- collapseFullCoverage(list(genomeData),
    verbose = TRUE
)
collapsedFull
## Not run:
## You can also collapsed the raw data
collapsedFullRaw <- collapseFullCoverage(list(genomeDataRaw), verbose = TRUE)

## End(Not run)
```

---

coverageToExon *Extract coverage information for exons*

Description

This function extracts the coverage information calculated by fullCoverage for a set of exons determined by makeGenomicState. The underlying code is similar to getRegionCoverage with additional tweaks for calculating RPKM values.

Usage

```
coverageToExon(
  fullCov = NULL,
  genomicState,
  L = NULL,
  returnType = "raw",
  files = NULL,
  ...
)
```

Arguments

fullCov	A list where each element is the result from loadCoverage used with returnCoverage = TRUE. Can be generated using fullCoverage. Alternatively, specify files to extract the coverage information from the regions of interest. This can be helpful if you do not wish to store fullCov for memory reasons.
genomicState	A GRanges object created with makeGenomicState. It can be either the genomicState$fullGenome or genomicState$codingGenome component.
L	The width of the reads used. Either a vector of length 1 or length equal to the number of samples.
returnType	If raw, then the raw coverage information per exon is returned. If rpkm, RPKM values are calculated for each exon.

`files` A character vector with the full path to the sample BAM files (or BigWig files). The names are used for the column names of the DataFrame. Check rawFiles for constructing `files`. `files` can also be a `BamFileList` object created with BamFileList or a `BigWigFileList` object created with BigWigFileList.

`...` Arguments passed to other methods and/or advanced arguments. Advanced arguments:

verbose If `TRUE` basic status updates will be printed along the way.

BPPARAM.strandStep A BPPARAM object to use for the strand step. If not specified, then `strandCores` specifies the number of cores to use for the strand step. The actual number of cores used is the minimum of `strandCores`, `mc.cores` and the number of strands in the data.

BPPARAM.chrStep A BPPRAM object to use for the chr step. If not specified, then `mc.cores` specifies the number of cores to use for the chr step. The actual number of cores used is the minimum of `mc.cores` and the number of samples.

Passed to extendedMapSeqlevels and define_cluster.

Details

Parallelization is used twice. First, it is used by strand. Second, for processing the exons by chromosome. So there is no gain in using `mc.cores` greater than the maximum of the number of strands and number of chromosomes.

If `fullCov` is `NULL` and `files` is specified, this function will attempt to read the coverage from the files. Note that if you used 'totalMapped' and 'targetSize' before, you will have to specify them again to get the same results.

Value

A matrix (nrow = number of exons in `genomicState` corresponding to the chromosomes in `fullCov`, ncol = number of samples) with the number of reads (or RPKM) per exon. The row names correspond to the row indexes of `genomicState$fullGenome` (if `fullOrCoding='full'`) or `genomicState$codingGenome` (if `fullOrCoding='coding'`).

Andrew Jaffe, Leonardo Collado-Torres

See Also

fullCoverage, getRegionCoverage

Examples

```
## Obtain fullCov object
fullCov <- list("21" = genomeDataRaw$coverage)

## Use only the first two exons
smallGenomicState <- genomicState
smallGenomicState$fullGenome <- smallGenomicState$fullGenome[
    which(smallGenomicState$fullGenome$theRegion == "exon")[1:2]
]

## Finally, get the coverage information for each exon
```

```
exonCov <- coverageToExon(
    fullCov = fullCov,
    genomicState = smallGenomicState$fullGenome, L = 36
)
```

---

createBw *Export coverage to BigWig files*

Description

Using output from fullCoverage, export the coverage from all the samples to BigWig files using createBwSample.

Usage

```
createBw(fullCov, path = ".", keepGR = TRUE, ...)
```

Arguments

fullCov	A list where each element is the result from loadCoverage used with returnCoverage = TRUE. Can be generated using fullCoverage.
path	The path where the BigWig files will be created.
keepGR	If TRUE, the GRanges objects created by coerceGR grouped into a GRangesList are returned. Otherwise they are discarded.
...	Arguments passed to createBwSample.

Details

Use at most one core per chromosome.

Value

If keepGR = TRUE, then a GRangesList with the output for coerceGR for each of the samples.

Examples

```
## Create a small fullCov object with data only for chr21
fullCov <- list("chr21" = genomeDataRaw)

## Keep only 2 samples
fullCov$chr21$coverage <- fullCov$chr21$coverage[c(1, 31)]

## Create the BigWig files for all samples in a test dir
dir.create("createBw-example")
```

```
bws <- createBw(fullCov, "createBw-example")

## Explore the output
bws

## First sample
bws[[1]]

## Note that if a sample has no bases with coverage > 0, the GRanges object
## is empty and no BigWig file is created for that sample.
bws[[2]]

## Exports fullCoverage() output to BigWig files
```

`createBwSample` *Create a BigWig file with the coverage information for a given sample*

Description

Given the output of fullCoverage, this function coerces the coverage to a GRanges object using coerceGR and then exports the coverage to a BigWig file using export.bw.

Usage

```
createBwSample(sample, path = ".", fullCov, keepGR = TRUE, ...)
```

Arguments

`sample`	The name or integer index of the sample of interest to coerce to a `GRanges` object.
`path`	The path where the BigWig file will be created.
`fullCov`	A list where each element is the result from loadCoverage used with `returnCoverage = TRUE`. Can be generated using fullCoverage.
`keepGR`	If `TRUE`, the GRanges object created by coerceGR is returned. Otherwise it is discarded.
`...`	Arguments passed to other methods and/or advanced arguments. Advanced arguments: **verbose** If `TRUE` basic status updates will be printed along the way. Passed to coerceGR.

Value

Creates a BigWig file with the coverage information (regions with coverage greater than zero) for a given sample. If `keepGR` it returns the output from coerceGR.

Author(s)

Leonardo Collado-Torres

See Also

GRanges, export.bw, linkcoerceGR

Examples

```
## Create a small fullCov object with data only for chr21
fullCov <- list("chr21" = genomeDataRaw)

## Create a BigWig for the first sample in a test directory
dir.create("createBwSample-example")
bw <- createBwSample("ERR009101", "createBwSample-example",
    fullCov = fullCov, seqlengths = c("chr21" = 48129895)
)

## Explore the output
bw

## Exports a single sample to a BigWig file
```

---

define_cluster *Define a cluster to use.*

Description

Define a cluster to use.

Usage

```
define_cluster(cores = "mc.cores", ...)
```

Arguments

cores	The argument to use to define the number of cores. This is useful for cases with nested parallelizations.
...	Advanced arguments are:
	mc.cores If 1 (default), then SerialParam will be used. If greater than 1, then it specifies the number of workers for SnowParam.
	mc.log Passed to log when using SnowParam.
	BPPARAM.custom If specified, that's the BPPARAM that will be used.

Details

This function is used internally in many functions.

Value

A BiocParallel *Param object

Author(s)

Leonardo Collado-Torres

Examples

```
## Use SerialParam()
define_cluster(mc.cores = 1)

## Note that BPPARAM.custom takes precedence
define_cluster(mc.cores = 2, BPPARAM.custom = BiocParallel::SerialParam())
```

`derfinder-deprecated` *Deprecated functions in package 'derfinder'*

Description

These functions are provided for compatibility with older version of 'derfinder' only and will be defunct at the next release.

Usage

```
advancedArg(fun, package = "derfinder", browse = interactive())
```

Arguments

`fun`	The name of a function(s) that has advanced arguments in package.
`package`	The name of the package where the function is stored. Only 'derfinder', 'derfinderPlot', and 'regionReport' are accepted.
`browse`	Whether to open the URLs in a browser.

Details

The following functions are deprecated and will be made defunct.

- advancedArg Not needed now that the advanced arguments are documented on the help pages of each function.

Value

A vector of URLs with the GitHub search queries.

Examples

```
## Open the advanced argument docs for loadCoverage()
if (interactive()) {
    advancedArg("loadCoverage")
} else {
    (advancedArg("loadCoverage", browse = FALSE))
}
```

`extendedMapSeqlevels` *Change naming style for a set of sequence names*

Description

If available, use the information from GenomeInfoDb for your species of interest to map the sequence names from the style currently used to another valid style. For example, for Homo sapiens map '2' (NCBI style) to 'chr2' (UCSC style). If the information from GenomeInfoDb is not available, the original sequence names will be returned. To disable this functionality specify set `chrsStyle` to `NULL`.

Usage

```
extendedMapSeqlevels(
  seqnames,
  style = getOption("chrsStyle", "UCSC"),
  species = getOption("species", "homo_sapiens"),
  currentStyle = NULL,
  ...
)
```

Arguments

`seqnames`	A character vector with the sequence names.
`style`	A single character vector specifying the naming style to use for renaming the sequence names.
`species`	A single character vector with the species of interest: it has to match the valid species names supported in GenomeInfoDb. See `names(GenomeInfoDb::genomeStyles())`. If `species = NULL`, a guess will be made using the available information in GenomeInfoDb.
`currentStyle`	A single character vector with the currently used naming style. If `NULL`, a guess will be made from the naming styles supported by `species`.
`...`	Arguments passed to other methods and/or advanced arguments. Advanced arguments: **verbose** If `TRUE` basic status updates will be printed along the way. **chrsStyle** The naming style of the chromosomes. By default, `UCSC`. See seqlevelsStyle. Set to `NULL` to disable this function. This is used when `style` is missing, which is normally the case when `extendedMapSeqlevels` is called by other functions.

Details

This function is inspired from mapSeqlevels with the difference that it will return the original sequence names if the species, current naming style or target naming style are not supported in GenomeInfoDb.

If you want to disable this function, set `chrsStyle` to `NULL`. From other functions in derfinder that pass the `...` argument to this function, use `chrsStyle = NULL`. This can be useful when working with organisms that are absent from GenomeInfoDb as documented in https://support.bioconductor.org/p/95521/.

Value

A vector of sequence names using the specified naming `style`.

Author(s)

L. Collado-Torres

Examples

```
## Without guessing any information
extendedMapSeqlevels("2", "UCSC", "Homo sapiens", "NCBI")

## Guessing the current naming style
extendedMapSeqlevels("2", "UCSC", "Homo sapiens")

## Guess species and current style
extendedMapSeqlevels("2", "NCBI")

## Guess species while supplying the current style.
## Probably an uncommon use-case
extendedMapSeqlevels("2", "NCBI", currentStyle = "TAIR10")

## Sequence names are unchanged when using an unsupported species
extendedMapSeqlevels("seq2", "NCBI", "toyOrganism")

## Disable extendedMapSeqlevels. This can be useful when working with
## organisms that are not supported by GenomeInfoDb
chrs <- c(
    "I", "II", "III", "IV", "IX", "V", "VI", "VII", "VIII", "X",
    "XI", "XII", "XIII", "XIV", "XV", "XVI", "XVII"
)
extendedMapSeqlevels(chrs, chrsStyle = NULL)
## Not run:
## Set global species and style option
options("chrsStyle" = "UCSC")
options("species" = "homo_sapiens")

## Run using global options
extendedMapSeqlevels("2")

## End(Not run)
```

`filterData` *Filter the positions of interest*

Description

For a group of samples this function reads the coverage information for a specific chromosome directly from the BAM files. It then merges them into a DataFrame and removes the bases that do not pass the cutoff. This is a helper function for loadCoverage and preprocessCoverage.

Usage

```
filterData(
  data,
  cutoff = NULL,
  index = NULL,
  filter = "one",
  totalMapped = NULL,
  targetSize = 8e+07,
  ...
)
```

Arguments

`data`	Either a list of Rle objects or a DataFrame with the coverage information.
`cutoff`	The base-pair level cutoff to use. It's behavior is controlled by `filter`.
`index`	A logical Rle with the positions of the chromosome that passed the cutoff. If `NULL` it is assumed that this is the first time using filterData and thus no previous index exists.
`filter`	Has to be either `'one'` (default) or `'mean'`. In the first case, at least one sample has to have coverage above `cutoff`. In the second case, the mean coverage has to be greater than `cutoff`.
`totalMapped`	A vector with the total number of reads mapped for each sample. The vector should be in the same order as the samples in `data`. Providing this data adjusts the coverage to reads in `targetSize` library prior to filtering. See getTotalMapped for calculating this vector.
`targetSize`	The target library size to adjust the coverage to. Used only when `totalMapped` is specified. By default, it adjusts to libraries with 80 million reads.
`...`	Arguments passed to other methods and/or advanced arguments. Advanced arguments: **verbose** If `TRUE` basic status updates will be printed along the way. **returnMean** If `TRUE` the mean coverage is included in the result. `FALSE` by default. **returnCoverage** If `TRUE`, the coverage DataFrame is returned. `TRUE` by default.

Details

If `cutoff` is `NULL` then the data is grouped into DataFrame without applying any cutoffs. This can be useful if you want to use loadCoverage to build the coverage DataFrame without applying any cutoffs for other downstream purposes like plotting the coverage values of a given region. You can always specify the `colsubset` argument in preprocessCoverage to filter the data before calculating the F statistics.

Value

A list with up to three components.

coverage is a DataFrame object where each column represents a sample. The number of rows depends on the number of base pairs that passed the cutoff and the information stored is the coverage at that given base. Included only when `returnCoverage = TRUE`.

position is a logical Rle with the positions of the chromosome that passed the cutoff.

meanCoverage is a numeric Rle with the mean coverage at each base. Included only when `returnMean = TRUE`.

colnames Specifies the column names to be used for the results DataFrame. If `NULL`, names from `data` are used.

smoothMean Whether to smooth the mean. Used only when `filter = 'mean'`. This option is used internally by regionMatrix.

Passed to the internal function `.smoother Fstats`, see findRegions.

loadCoverage, preprocessCoverage, getTotalMapped

Examples

```
## Construct some toy data
library("IRanges")
x <- Rle(round(runif(1e4, max = 10)))
y <- Rle(round(runif(1e4, max = 10)))
z <- Rle(round(runif(1e4, max = 10)))
DF <- DataFrame(x, y, z)

## Filter the data
filt1 <- filterData(DF, 5)
filt1

## Filter again but only using the first two samples
filt2 <- filterData(filt1$coverage[, 1:2], 5, index = filt1$position)
filt2
```

---

findRegions *Find non-zero regions in a Rle*

Description

Find genomic regions for which a numeric vector is above (or below) predefined thresholds. In other words, this function finds the candidate Differentially Expressed Regions (candidate DERs). This is similar to regionFinder and is a helper function for calculatePvalues.

Usage

```
findRegions(
  position = NULL,
  fstats,
  chr,
  oneTable = TRUE,
  maxClusterGap = 300L,
  cutoff = quantile(fstats, 0.99, na.rm = TRUE),
```

```
  segmentIR = NULL,
  smooth = FALSE,
  weights = NULL,
  smoothFunction = bumphunter::locfitByCluster,
  ...
)
```

Arguments

position	A logical Rle of genomic positions. This is generated in loadCoverage. Note that it gets updated in preprocessCoverage if colsubset is not NULL.
fstats	A numeric Rle with the F-statistics. Usually obtained using calculateStats.
chr	A single element character vector specifying the chromosome name.
oneTable	If TRUE only one GRanges is returned. Otherwise, a GRangesList with two components is returned: one for the regions with positive values and one for the negative values.
maxClusterGap	This determines the maximum gap between candidate DERs. It should be greater than maxRegionGap (0 by default).
cutoff	Threshold applied to the fstats used to determine the regions.
segmentIR	An IRanges object with the genomic positions that are potentials DERs. This is used in calculatePvalues to speed up permutation calculations.
smooth	Whether to smooth the F-statistics (fstats) or not. This is by default FALSE. For RNA-seq data we recommend using FALSE.
weights	Weights used by the smoother as described in smoother.
smoothFunction	A function to be used for smoothing the F-statistics. Two functions are provided by the bumphunter package: loessByCluster and runmedByCluster. If you are using your own custom function, it has to return a named list with an element called $fitted that contains the smoothed F-statistics and an element claled $smoothed that is a logical vector indicating whether the F-statistics were smoothed or not. If they are not smoothed, the original values will be used.
...	Arguments passed to other methods and/or advanced arguments. Advanced arguments: **verbose** If TRUE basic status updates will be printed along the way. **basic** If TRUE a DataFrame is returned that has only basic information on the candidate DERs. This is used in calculatePvalues to speed up permutation calculations. Default: FALSE. **maxRegionGap** This determines the maximum number of gaps between two genomic positions to be considered part of the same candidate region. The default is 0L. Passed to extendedMapSeqlevels and the internal function .getSegmentsRle that has by default verbose = FALSE. When smooth = TRUE, ... is passed to the internal function .smootherFstats. This internal function has the advanced argument maxClusterGap (same as above) and passes ... to define_cluster and the formal arguments of smoothFun.

Details

regionFinder adapted to Rle world.

Value

Either a GRanges or a GRangesList as determined by `oneTable`. Each of them has the following metadata variables.

value The mean of the values of `y` for the given region.

area The absolute value of the sum of the values of `y` for the given region.

indexStart The start position of the region in terms of the index for `y`.

indexEnd The end position of the region in terms of the index for `y`.

cluster The cluser ID.

clusterL The total length of the cluster.

```

`fullCoverage` *Load the unfiltered coverage information from a group of BAM files and a list of chromosomes*

Description

For a group of samples this function reads the coverage information for several chromosomes directly from the BAM files. Per chromosome, it merges the unfiltered coverage by sample into a DataFrame. The end result is a list with one such DataFrame objects per chromosome.

Usage

```
fullCoverage(
  files,
  chrs,
  bai = NULL,
  chrlens = NULL,
  outputs = NULL,
  cutoff = NULL,
  ...
)
```

Arguments

`files`	A character vector with the full path to the sample BAM files (or BigWig files). The names are used for the column names of the DataFrame. Check rawFiles for constructing `files`. `files` can also be a `BamFileList` object created with BamFileList or a `BigWigFileList` object created with BigWigFileList.
`chrs`	The chromosome of the files to read. The format has to match the one used in the input files.
`bai`	The full path to the BAM index files. If `NULL` it is assumed that the BAM index files are in the same location as the BAM files and that they have the .bai extension. Ignored if `files` is a `BamFileList` object.
`chrlens`	The chromosome lengths in base pairs. If it's `NULL`, the chromosome length is extracted from the BAM files. Otherwise, it should have the same length as `chrs`.
`outputs`	This argument is passed to the `output` argument of loadCoverage. If `NULL` or `'auto'` it is then recycled.
`cutoff`	This argument is passed to filterData.
`...`	Arguments passed to other methods and/or advanced arguments. Advanced arguments: **verbose** If `TRUE` basic status updates will be printed along the way. **mc.cores** How many cores to use for reading the chromosome information. There's no benefit of using a number greater than the number of chromosomes. Also note that your harddisk speed will limit how much you get from using a higher `mc.cores` value.

mc.cores.load Controls the number of cores to be used per chr for loading the data which is only useful in the scenario that you are loading in genome tiles. If not supplied, it uses `mc.cores` for loadCoverage. Default: 1. If you are using genome tiles, the total number of cores you'll use will be `mc.cores` times `mc.cores.load`.

Passed to loadCoverage, define_cluster and extendedMapSeqlevels. Note that filterData is used internally by loadCoverage (and hence fullCoverage) and has the important arguments `totalMapped` and `targetSize` which can be used to normalize the coverage by library size. See getTotalMapped for calculating `totalMapped`.

Value

A list with one element per chromosome.

Each element is a DataFrame with the coverage information produced by loadCoverage.

Author(s)

Leonardo Collado-Torres

See Also

loadCoverage, filterData, getTotalMapped

Examples

```
datadir <- system.file("extdata", "genomeData", package = "derfinder")
files <- rawFiles(
    datadir = datadir, samplepatt = "*accepted_hits.bam$",
    fileterm = NULL
)
## Shorten the column names
names(files) <- gsub("_accepted_hits.bam", "", names(files))

## Read and filter the data, only for 1 file
fullCov <- fullCoverage(files = files[1], chrs = c("21", "22"))
fullCov
## Not run:
## You can then use filterData() to filter the data if you want to.
## Use bplapply() if you want to do so with multiple cores as shown below.
library("BiocParallel")
p <- SnowParam(2L)
bplapply(fullCov, function(x) {
    library("derfinder")
    filterData(x, cutoff = 0)
}, BPPARAM = p)

## End(Not run)
```

genomeData *Genome samples processed data*

Description

10kb region from chr21 processed for 31 RNA-seq samples described in genomeInfo. The TopHat BAM files are included in the package and this is the output of loadCoverage applied to it. For more information check the example of loadCoverage.

Format

A list with two components.

coverage is a DataFrame object where each column represents a sample.

position is a logical Rle with the positions of the chromosome that passed a cutoff of 0.

genomeDataRaw *Genome samples processed data*

Description

10kb region from chr21 processed for 31 RNA-seq samples described in genomeInfo. The TopHat BAM files are included in the package and this is the output of loadCoverage applied to it with `cutoff=NULL`. For more information check the example of loadCoverage.

Format

A list with two components.

coverage is a DataFrame object where each column represents a sample.

position is `NULL` because no bases were filtered.

loadCoverage, genomeInfo

`genomeFstats` *F-statistics for the example data*

Description

Calculated F-statistics for a 10kb region from chr21 processed for 31 RNA-seq samples described in genomeInfo. For more information check the example of calculateStats.

Format

A numeric Rle of length 1434 with the calculated F-statistics as exemplified in calculateStats.

See Also

calculateStats

`genomeInfo` *Genome samples information*

Description

Information for the 31 samples downloaded from the Short Read Archive from studies comparing CEU and YRI populations. This data is used to specify the adjustment variables in calculateStats. The data is sorted according to the BAM files identifiers. Reads were 36bp long.

Format

A data.frame with 5 columns:

run The short name used to identify the sample BAM file.

library.layout Whether it was a single-end library or a paired-end library.

hapmap.id The HapMap identifier of the person sequenced. Note that some were sequenced more than once.

gender Whether the person sequence is a female or a male.

pop The population the person belongs to.

Details

The samples are from:

10 unrelated females from the YRI population.

5 unrelated females from the CEU population.

5 unrelated males (unrelated to the females too) from the CEU population.

References

1. Pickrell JK, Marioni JC, Pai AA, Degner JF, Engelhardt BE, Nkadori E, Veyrieras J-B, Stephens M, Gilad Y, Pritchard JK. Understanding mechanisms underlying human gene expression variation with RNA sequencing. Nature 2010 Apr.

genomeRegions *Candidate DERs for example data*

Description

Candidate Differentially Expressed Regions (DERs) for the example data. For more information check calculatePvalues.

Format

A list with four components.

regions a GRanges object with the candidate DERs.

nullStats a numeric Rle with the mean F-statistics for the null DERs found from the permutations.

nullWidths an integer Rle with the width of each null candidate DER.

nullPermutation an integer Rle with the permutation number for each candidate DER. It identifies which permutation cycle created the null candidate DER.

See Also

calculatePvalues

genomicState *Genomic State for Hsapiens.UCSC.hg19.knownGene*

Description

Pre-computed genomic state for Hsapiens UCSC hg19 knownGene annotation built using makeGenomicState for TxDb.Hsapiens.UCSC.hg19.knownGene version 2.14.0. The object has been subset for chr21 only.

Format

A GRangesList with two components.

fullGenome classifies each region as either being exon, intron or intergenic.

codingGenome classfies the regions as being promoter, exon, intro, 5UTR, 3UTR or intergenic.

See Also

makeGenomicState

getRegionCoverage *Extract coverage information for a set of regions*

Description

This function extracts the raw coverage information calculated by fullCoverage at each base for a set of regions found with calculatePvalues. It can further calculate the mean coverage per sample for each region.

Usage

```
getRegionCoverage(
  fullCov = NULL,
  regions,
  totalMapped = NULL,
  targetSize = 8e+07,
  files = NULL,
  ...
)
```

Arguments

`fullCov`	A list where each element is the result from loadCoverage used with `returnCoverage = TRUE`. Can be generated using fullCoverage. Alternatively, specify `files` to extract the coverage information from the regions of interest. This can be helpful if you do not wish to store `fullCov` for memory reasons.
`regions`	The `$regions` output from calculatePvalues. It is important that the seqlengths information is provided.

`totalMapped` The total number of reads mapped for each sample. Providing this data adjusts the coverage to reads in `targetSize` library. By default, to reads per 80 million reads.

`targetSize` The target library size to adjust the coverage to. Used only when `totalMapped` is specified.

`files` A character vector with the full path to the sample BAM files (or BigWig files). The names are used for the column names of the DataFrame. Check rawFiles for constructing `files`. `files` can also be a `BamFileList` object created with BamFileList or a `BigWigFileList` object created with BigWigFileList.

`...` Arguments passed to other methods and/or advanced arguments. Advanced arguments:

verbose If `TRUE` basic status updates will be printed along the way.

Passed to extendedMapSeqlevels and define_cluster.

When `fullCov` is `NULL`, `...` has the advanced argument `protectWhich` (default 30000) from loadCoverage. Also `...` is passed to fullCoverage for loading the data on the fly. This can be useful for loading the data from a specific region (or small sets of regions) without having to load in memory the output the coverage information from all the genome.

Details

When `fullCov` is the output of loadCoverage with `cutoff` non-NULL, getRegionCoverage assumes that the regions come from the same data. Meaning that filterData was not used again. This ensures that the regions are a subset of the data available in `fullCov`.

If `fullCov` is `NULL` and `files` is specified, this function will attempt to read the coverage from the files. Note that if you used 'totalMapped' and 'targetSize' before, you will have to specify them again to get the same results.

You should use at most one core per chromosome.

Value

a list of data.frame where each data.frame has the coverage information (nrow = width of region, ncol = number of samples) for a given region. The names of the list correspond to the region indexes in `regions`

Author(s)

Andrew Jaffe, Leonardo Collado-Torres

See Also

fullCoverage, calculatePvalues

Examples

```
## Obtain fullCov object
fullCov <- list("21" = genomeDataRaw$coverage)

## Assign chr lengths using hg19 information, use only first two regions
library("GenomeInfoDb")  # for getChromInfoFromUCSC()
regions <- genomeRegions$regions[1:2]
seqlengths(regions) <- seqlengths(getChromInfoFromUCSC("hg19",
```

```
    as.Seqinfo = TRUE
))[
    mapSeqlevels(names(seqlengths(regions)), "UCSC")
]

## Finally, get the region coverage
regionCov <- getRegionCoverage(fullCov = fullCov, regions = regions)
```

`getTotalMapped` *Calculate the total number of mapped reads*

Description

For a given BAM calculate the total number of mapped reads and for a BigWig file calculate the area under the curve (AUC), which is related to the number of mapped reads: the exact relationship depends on whether the aligner soft clips reads and/or if the length of the reads is the same. If you use the 'chrs' argument you can choose to only consider the information for your chromosomes of interest. For example, you can exclude the mitocondrial chromosome.

Usage

```
getTotalMapped(rawFile, chrs = NULL)
```

Arguments

`rawFile`	Either a BAM file or a BigWig file.
`chrs`	If `NULL`, all the chromosomes will be used. Otherwise, only those in `chrs` will be used.

Value

The total number of mapped reads for a BAM file or the AUC for a BigWig file in a single element vector.

Author(s)

Leonardo Collado-Torres

Examples

```
## Get the total number of mapped reads for an example BAM file:
bam <- system.file("extdata", "genomeData", "ERR009102_accepted_hits.bam",
    package = "derfinder", mustWork = TRUE
)
getTotalMapped(bam)
```

loadCoverage *Load the coverage information from a group of BAM files*

Description

For a group of samples this function reads the coverage information for a specific chromosome directly from the BAM files. It then merges them into a DataFrame and removes the bases that do not pass the cutoff.

Usage

```
loadCoverage(
  files,
  chr,
  cutoff = NULL,
  filter = "one",
  chrlen = NULL,
  output = NULL,
  bai = NULL,
  ...
)
```

Arguments

files	A character vector with the full path to the sample BAM files (or BigWig files). The names are used for the column names of the DataFrame. Check rawFiles for constructing `files`. `files` can also be a BamFileList, BamFile, BigWigFileList, or BigWigFile object.
chr	Chromosome to read. Should be in the format matching the one used in the raw data.
cutoff	This argument is passed to filterData.
filter	Has to be either `'one'` (default) or `'mean'`. In the first case, at least one sample has to have coverage above `cutoff`. In the second case, the mean coverage has to be greater than `cutoff`.
chrlen	The chromosome length in base pairs. If it's `NULL`, the chromosome length is extracted from the BAM files.
output	If `NULL` then no output is saved in disk. If `auto` then an automatic name is constructed using UCSC names (chrXCovInfo.Rdata for example). If another character is specified, then that name is used for the output file.
bai	The full path to the BAM index files. If `NULL` it is assumed that the BAM index files are in the same location as the BAM files and that they have the .bai extension. Ignored if `files` is a `BamFileList` object or if `inputType=='BigWig'`.
...	Arguments passed to other methods and/or advanced arguments. Advanced arguments: **verbose** If `TRUE` basic status updates will be printed along the way. **inputType** Has to be either `bam` or `BigWig`. It specifies the format of the raw data files. By default it's set to `bam` before trying to guess it from the file names.

tilewidth When specified, tileGenome is used to break up the chromosome into chunks. We don't recommend this for BAM files as the coverage in the borders of the chunks might be slightly off.

which `NULL` by default. When a `GRanges` is specified, this specific region of the genome is loaded instead of the full chromosome.

fileStyle The naming style of the chromosomes in the input files. If the global option `chrsStyle` is not set, the naming style won't be changed. This option is useful when you want to use a specific naming style but the raw files use another style.

protectWhich When not `NULL` and `which` is specified, this argument specifies by how much the ranges in `which` will be expanded. This helps get the same base level coverage you would get from reading the coverage for a full chromosome from BAM files. Otherwise some reads might be excluded and thus the base level coverage will be lower. `NULL` by default.

drop.D Whether to drop the bases with 'D' in the CIGAR strings or to include them. Only used with BAM files. `FALSE` by default.

sampleNames Column names to be used the samples. By default it's `names(files)`.

Passed to extendedMapSeqlevels, define_cluster, scanBamFlag and filterData. Note that filterData is used internally by loadCoverage and has the important arguments `totalMapped` and `targetSize` which can be used to normalize the coverage by library size. See getTotalMapped for calculating `totalMapped`.

Details

The ... argument can be used to control which alignments to consider when reading from BAM files. See scanBamFlag.

Parallelization for loading the data in chunks is used only used when `tilewidth` is specified. You may use up to one core per tile.

If you set the advanced argument `drop.D = TRUE`, bases with CIGAR string "D" (deletion from reference) will be excluded from the base-level coverage calculation.

If you are working with data from an organism different from 'Homo sapiens' specify so by setting the global 'species' and 'chrsStyle' options. For example: `options(species = 'arabidopsis_thaliana')` `options(chrsStyle = 'NCBI')`

Value

A list with two components.

coverage is a DataFrame object where each column represents a sample. The number of rows depends on the number of base pairs that passed the cutoff and the information stored is the coverage at that given base.

position is a logical Rle with the positions of the chromosome that passed the cutoff.

Examples

```
datadir <- system.file("extdata", "genomeData", package = "derfinder")
files <- rawFiles(
    datadir = datadir, samplepatt = "*accepted_hits.bam$",
    fileterm = NULL
)
## Shorten the column names
names(files) <- gsub("_accepted_hits.bam", "", names(files))

## Read and filter the data, only for 2 files
dataSmall <- loadCoverage(files = files[1:2], chr = "21", cutoff = 0)
## Not run:
## Export to BigWig files
createBw(list("chr21" = dataSmall))

## Load data from BigWig files
dataSmall.bw <- loadCoverage(c(
    ERR009101 = "ERR009101.bw", ERR009102 =
        "ERR009102.bw"
), chr = "chr21")

## Compare them
mapply(function(x, y) {
    x - y
}, dataSmall$coverage, dataSmall.bw$coverage)

## Note that the only difference is the type of Rle (integer vs numeric) used
## to store the data.

## End(Not run)
```

`makeGenomicState` *Obtain the genomic state per region from annotation*

Description

This function summarizes the annotation contained in a TxDb at each given base of the genome based on annotated transcripts. It groups contiguous base pairs classified as the same type into regions.

Usage

```
makeGenomicState(txdb, chrs = c(seq_len(22), "X", "Y"), ...)
```

Arguments

`txdb`	A TxDb object with chromosome lengths (check `seqlengths(txdb)`). If you are using a TxDb object created from a GFF/GTF file, you will find this https://support.bioconductor.org/p/93235/ useful.
`chrs`	The names of the chromosomes to use as denoted in the `txdb` object. Check isActiveSeq.
`...`	Arguments passed to extendedMapSeqlevels.

Value

A GRangesList object with two elements: fullGenome and codingGenome. Both have metadata information for the type of region (theRegion), transcript IDs (tx_id), transcript name (tx_name), and gene ID (gene_id). fullGenome classifies each region as either being exon, intron or intergenic. codingGenome classfies the regions as being promoter, exon, intro, 5UTR, 3UTR or intergenic.

## End(Not run)
```

`makeModels` *Build model matrices for differential expression*

Description

Builds the model matrices for testing for differential expression by comparing a model with a grouping factor versus one without it. It adjusts for the confounders specified and the median coverage of each sample. The resulting models can be used in calculateStats.

Usage

```
makeModels(sampleDepths, testvars, adjustvars = NULL, testIntercept = FALSE)
```

Arguments

`sampleDepths`	Per sample library size adjustments calculated with sampleDepth.
`testvars`	A vector or matrix specifying the variables to test. For example, a factor with the group memberships when testing for differences across groups. It's length should match the number of columns used from `coverageInfo$coverage`.
`adjustvars`	Optional matrix of adjustment variables (e.g. measured confounders, output from SVA, etc.) to use in fitting linear models to each nucleotide. These variables have to be specified by sample and the number of rows must match the number of columns used. It will also work if it is a vector of the correct length.
`testIntercept`	If `TRUE` then `testvars` is ignored and mod0 will contain the column medians and any adjusting variables specified, but no intercept.

Value

A list with two components.

mod The alternative model matrix.

mod0 The null model matrix.

adjustvars <- data.frame(genomeInfo$gender)
models <- makeModels(sampleDepths, testvars = group, adjustvars = adjustvars)
names(models)
models
```

`mergeResults` *Merge results from different chromosomes*

Description

This function merges the results from running analyzeChr on several chromosomes and assigns genomic states using annotateRegions. It re-calculates the p-values and q-values using the pooled areas from the null regions from all chromosomes. Once the results have been merged, `derfinderReport::generateRepo` can be used to generate an HTML report of the results. The `derfinderReport` package is available at https://github.com/lcolladotor/derfinderReport.

Usage

```
mergeResults(
  chrs = c(seq_len(22), "X", "Y"),
  prefix = ".",
  significantCut = c(0.05, 0.1),
  genomicState,
  minoverlap = 20,
  mergePrep = FALSE,
  ...
)
```

Arguments

`chrs`	The chromosomes of the files to be merged.
`prefix`	The main data directory path, which can be useful if analyzeChr is used for several parameters and the results are saved in different directories.
`significantCut`	A vector of length two specifiying the cutoffs used to determine significance. The first element is used to determine significance for the P-values and FWER adjusted P-values, while the second element is used for the Q-values (FDR adjusted P-values) similar to calculatePvalues.

`genomicState` A GRanges object created with makeGenomicState. It can be either the `genomicState$fullGenome` or `genomicState$codingGenome` component.

`minoverlap` Determines the mininum overlap needed when annotating regions with annotateRegions.

`mergePrep` If `TRUE` the output from preprocessCoverage is merged.

`...` Arguments passed to other methods and/or advanced arguments. Advanced arguments:

verbose If `TRUE` basic status updates will be printed along the way.

optionsStats The options used in analyzeChr. By default `NULL` and will be inferred from the output files.

cutoffFstatUsed The actual F-statistic cutoff used. This can be obtained from the logs or from the output of analyzeChr. If `NULL` then this function will attempt to re-calculate it.

Passed to annotateRegions and extendedMapSeqlevels.

Details

If you want to calculate the FWER adjusted P-values, supply `optionsStats` which is produced by analyzeChr.

Value

Seven Rdata files.

fullFstats.Rdata Full F-statistics from all chromosomes in a list of Rle objects.

fullTime.Rdata Timing information from all chromosomes.

fullNullSummary.Rdata A DataFrame with the null region information: statistic, width, chromosome and permutation identifier. It's ordered by the statistics

fullRegions.Rdata GRanges object with regions found and with full annotation from matchGenes. Note that the column `strand` from matchGenes is renamed to `annoStrand` to comply with GRanges specifications.

fullCoveragePrep.Rdata A list with the pre-processed coverage data from all chromosomes.

fullAnnotatedRegions.Rdata A list as constructed in annotateRegions with the assigned genomic states.

optionsMerge.Rdata A list with the options used when merging the results. Used in `derfinderReport::generateRepo`

    scale_x_discrete(limits = names(fullTime[[1]])[-1]) +
    ylab("Time (min)") +
    xlab("Step")

## End(Not run)
```

`preprocessCoverage` *Transform and split the data*

Description

This function takes the coverage data from loadCoverage, scales the data, does the log2 transformation, and splits it into appropriate chunks for using calculateStats.

Usage

```
preprocessCoverage(
  coverageInfo,
  groupInfo = NULL,
  cutoff = 5,
  colsubset = NULL,
  lowMemDir = NULL,
  ...
)
```

Arguments

coverageInfo	A list containing a DataFrame –$coverage– with the coverage data and a logical Rle –$position– with the positions that passed the cutoff. This object is generated using loadCoverage. You should have specified a cutoff value for loadCoverage unless that you are using colsubset which will force a filtering step with filterData when running preprocessCoverage.
groupInfo	A factor specifying the group membership of each sample. If NULL no group mean coverages are calculated. If the factor has more than one level, the first one will be used to calculate the log2 fold change in calculatePvalues.
cutoff	The base-pair level cutoff to use. It's behavior is controlled by filter.
colsubset	Optional vector of column indices of coverageInfo$coverage that denote samples you wish to include in analysis.
lowMemDir	If specified, each chunk is saved into a separate Rdata file under lowMemDir and later loaded in fstats.apply when running calculateStats and calculatePvalues. Using this option helps reduce the memory load as each fork in bplapply loads only the data needed for the chunk processing. The downside is a bit longer computation time due to input/output.
...	Arguments passed to other methods and/or advanced arguments. Advanced arguments: **verbose** If TRUE basic status updates will be printed along the way. Default: FALSE. **toMatrix** Determines whether the data in the chunk should already be saved as a Matrix object, which can be useful to reduce the computation time of the F-statistics. Only used when lowMemDir is not NULL and by in that case set to TRUE by default. **mc.cores** Number of cores you will use for calculating the statistics. **scalefac** A log 2 transformation is used on the count tables, so zero counts present a problem. What number should we add to the entire matrix? Default: 32. **chunksize** How many rows of coverageInfo$coverage should be processed at a time? Default: 5 million. Reduce this number if you have hundreds of samples to reduce the memory burden while sacrificing some speed.

Details

If chunksize is NULL, then mc.cores is used to determine the chunksize. This is useful if you want to split the data so each core gets the same amount of data (up to rounding).

Computing the indexes and using those for mclapply reduces memory copying as described by Ryan Thompson and illustrated in approach #4 at http://lcolladotor.github.io/2013/11/14/Reducing-memory-overhead-when-using-mclapply

If lowMemDir is specified then $coverageProcessed is NULL and $mclapplyIndex is a vector with the chunk identifiers.

Value

A list with five components.

coverageProcessed contains the processed coverage information in a DataFrame object. Each column represents a sample and the coverage information is scaled and log2 transformed. Note that if colsubset is not NULL the number of columns will be less than those in coverageInfo$coverage.

The total number of rows depends on the number of base pairs that passed the `cutoff` and the information stored is the coverage at that given base. Further note that filterData is re-applied if `colsubset` is not `NULL` and could thus lead to fewer rows compared to `coverageInfo$coverage`.

mclapplyIndex is a list of logical Rle objects. They contain the partioning information according to `chunksize`.

position is a logical Rle with the positions of the chromosome that passed the cutoff.

meanCoverage is a numeric Rle with the mean coverage at each filtered base.

groupMeans is a list of Rle objects containing the mean coverage at each filtered base calculated by group. This list has length 0 if `groupInfo=NULL`.

Passed to filterData when `colsubset` is specified.

)
names(dataReady)
dataReady
```

`railMatrix` *Identify regions data by a coverage filter and get a count matrix from BigWig files*

Description

Rail (available at http://rail.bio) generates coverage BigWig files. These files are faster to load in R and to process. Rail creates an un-adjusted coverage BigWig file per sample and an adjusted summary coverage BigWig file by chromosome (median or mean). railMatrix reads in the mean (or median) coverage BigWig file and applies a threshold cutoff to identify expressed regions (ERs). Then it goes back to the sample coverage BigWig files and extracts the base level coverage for each sample. Finally it summarizes this information in a matrix with one row per ERs and one column per sample. This function is similar to regionMatrix but is faster thanks to the advantages presented by BigWig files.

Usage

```
railMatrix(
  chrs,
  summaryFiles,
  sampleFiles,
  L,
  cutoff = NULL,
  maxClusterGap = 300L,
  totalMapped = NULL,
  targetSize = 4e+07,
  file.cores = 1L,
  chrlens = NULL,
  ...
)
```

Arguments

chrs	A character vector with the names of the chromosomes.
summaryFiles	A character vector (or BigWigFileList) with the paths to the summary BigWig files created by Rail. Either mean or median files. These are library size adjusted by default in Rail. The order of the files in this vector must match the order in chrs.
sampleFiles	A character vector with the paths to the BigWig files by sample. These files are unadjusted for library size.
L	The width of the reads used. Either a vector of length 1 or length equal to the number of samples.
cutoff	The base-pair level cutoff to use. It's behavior is controlled by filter.
maxClusterGap	This determines the maximum gap between candidate ERs.
totalMapped	A vector with the total number of reads mapped for each sample. The vector should be in the same order as the samples in data. Providing this data adjusts the coverage to reads in targetSize library prior to filtering. See getTotalMapped for calculating this vector.
targetSize	The target library size to adjust the coverage to. Used only when totalMapped is specified. By default, it adjusts to libraries with 40 million reads, which matches the default used in Rail.
file.cores	Number of cores used for loading the BigWig files per chr.
chrlens	The chromosome lengths in base pairs. If it's NULL, the chromosome length is extracted from the BAM files. Otherwise, it should have the same length as chrs.
...	Arguments passed to other methods and/or advanced arguments. Advanced arguments: **verbose** If TRUE basic status updates will be printed along the way. Default: TRUE. **verbose.load** If TRUE basic status updates will be printed along the way when loading data. Default: TRUE. **BPPARAM.railChr** A BPPARAM object to use for the chr step. Set to SerialParam when file.cores = 1 and SnowParam otherwise. **chunksize** Chunksize to use. Default: 1000. Passed to filterData, findRegions and define_cluster.

Details

Given a set of un-filtered coverage data (see fullCoverage), create candidate regions by applying a cutoff on the coverage values, and obtain a count matrix where the number of rows corresponds to the number of candidate regions and the number of columns corresponds to the number of samples. The values are the mean coverage for a given sample for a given region.

This function uses several other derfinder-package functions. Inspect the code if interested.

You should use at most one core per chromosome.

Value

A list with one entry per chromosome. Then per chromosome, a list with two components.

regions A set of regions based on the coverage filter cutoff as returned by findRegions.

coverageMatrix A matrix with the mean coverage by sample for each candidate region.

Author(s)

Leonardo Collado-Torres

Examples

```
## BigWig files are not supported in Windows
if (.Platform$OS.type != "windows") {
    ## Get data
    library("derfinderData")

    ## Identify sample files
    sampleFiles <- rawFiles(system.file("extdata", "AMY",
        package =
            "derfinderData"
    ), samplepatt = "bw", fileterm = NULL)
    names(sampleFiles) <- gsub(".bw", "", names(sampleFiles))

    ## Create the mean bigwig file. This file is normally created by Rail
    ## but in this example we'll create it manually.
    library("GenomicRanges")
    fullCov <- fullCoverage(files = sampleFiles, chrs = "chr21")
    meanCov <- Reduce("+", fullCov$chr21) / ncol(fullCov$chr21)
    createBw(list("chr21" = DataFrame("meanChr21" = meanCov)),
        keepGR =
            FALSE
    )

    summaryFile <- "meanChr21.bw"

    ## Get the regions
    regionMat <- railMatrix(
        chrs = "chr21", summaryFiles = summaryFile,
        sampleFiles = sampleFiles, L = 76, cutoff = 5.1,
        maxClusterGap = 3000L
    )

    ## Explore results
    names(regionMat$chr21)
    regionMat$chr21$regions
```

```
    dim(regionMat$chr21$coverageMatrix)
}
```

`rawFiles` *Construct full paths to a group of raw input files*

Description

For a group of samples this function creates the list of paths to the raw input files which can then be used in loadCoverage. The raw input files are either BAM files or BigWig files.

Usage

```
rawFiles(
  datadir = NULL,
  sampledirs = NULL,
  samplepatt = NULL,
  fileterm = "accepted_hits.bam"
)
```

Arguments

`datadir`	The main directory where each of the `sampledirs` is a sub-directory of `datadir`.
`sampledirs`	A character vector with the names of the sample directories. If `datadir` is `NULL` it is then assumed that `sampledirs` specifies the full path to each sample.
`samplepatt`	If specified and `sampledirs` is set to `NULL`, then the directories matching this pattern in `datadir` (set to `.` if it's set to `NULL`) are used as the sample directories.
`fileterm`	Name of the BAM or BigWig file used in each sample. By default it is set to `accepted_hits.bam` since that is the automatic name generated when aligning with TopHat. If `NULL` it is then ignored when reading the rawfiles. This can be useful if all the raw files are stored in a single directory.

Details

This function can also be used to identify a set of BigWig files.

Value

A vector with the full paths to the raw files and sample names stored as the vector names.

Author(s)

Leonardo Collado-Torres

    datadir = datadir, samplepatt = "*accepted_hits.bam$",
    fileterm = NULL
)
files
```

`regionMatrix` *Identify regions data by a coverage filter and get a count matrix*

Description

Given a set of un-filtered coverage data (see fullCoverage), create candidate regions by applying a cutoff on the coverage values, and obtain a count matrix where the number of rows corresponds to the number of candidate regions and the number of columns corresponds to the number of samples. The values are the mean coverage for a given sample for a given region.

Usage

```
regionMatrix(
  fullCov,
  cutoff = 5,
  L,
  totalMapped = 8e+07,
  targetSize = 8e+07,
  runFilter = TRUE,
  returnBP = TRUE,
  ...
)
```

Arguments

`fullCov`	A list where each element is the result from loadCoverage used with `returnCoverage = TRUE`. Can be generated using fullCoverage. If `runFilter = FALSE`, then `returnMean = TRUE` must have been used.
`cutoff`	The base-pair level cutoff to use. It's behavior is controlled by `filter`.
`L`	The width of the reads used. Either a vector of length 1 or length equal to the number of samples.
`totalMapped`	A vector with the total number of reads mapped for each sample. The vector should be in the same order as the samples in `fullCov`. Providing this argument adjusts the coverage to reads in `targetSize` library prior to filtering. See getTotalMapped for calculating this vector.
`targetSize`	The target library size to adjust the coverage to. Used only when `totalMapped` is specified. By default, it adjusts to libraries with 80 million reads.
`runFilter`	This controls whether to run filterData or not. If set to `FALSE` then `returnMean = TRUE` must have been used to create each element of `fullCov` and the data must have been normalized (`totalMapped` equal to `targetSize`).

`returnBP` If `TRUE`, returns `$bpCoverage` explained below.

`...` Arguments passed to other methods and/or advanced arguments. Advanced arguments:

verbose If `TRUE` basic status updates will be printed along the way.

chrsStyle Default: `UCSC`. Passed to extendedMapSeqlevels via getRegionCoverage.

species Default: `homo_sapiens`. Passed to extendedMapSeqlevels via getRegionCoverage.

currentStyle Default: `NULL`. Passed to extendedMapSeqlevels via getRegionCoverage.

Passed to filterData, findRegions and define_cluster.

Note that filterData is used internally by loadCoverage (and hence `fullCoverage`) and has the important arguments `totalMapped` and `targetSize` which can be used to normalize the coverage by library size. If you already used these arguments when creating the `fullCov` object, then don't specify them a second time in regionMatrix. If you have not used these arguments, we recommend using them to normalize the mean coverage.

Details

This function uses several other derfinder-package functions. Inspect the code if interested.

You should use at most one core per chromosome.

Value

A list with one entry per chromosome. Then per chromosome, a list with three components.

regions A set of regions based on the coverage filter cutoff as returned by findRegions.

bpCoverage A list with one element per region. Each element is a matrix with numbers of rows equal to the number of base pairs in the region and number of columns equal to the number of samples. It contains the base-level coverage information for the regions. Only returned when `returnBP = TRUE`.

coverageMatrix A matrix with the mean coverage by sample for each candidate region.

Author(s)

Leonardo Collado-Torres

Examples

```
## Create some toy data
library("IRanges")
x <- Rle(round(runif(1e4, max = 10)))
y <- Rle(round(runif(1e4, max = 10)))
z <- Rle(round(runif(1e4, max = 10)))
fullCov <- list("chr21" = DataFrame(x, y, z))

## Calculate a proxy of library size
libSize <- sapply(fullCov$chr21, sum)

## Run region matrix normalizing the coverage
regionMat <- regionMatrix(
```

```
    fullCov = fullCov, maxRegionGap = 10L,
    maxClusterGap = 300L, L = 36, totalMapped = libSize, targetSize = 4e4
)
## Not run:
## You can alternatively use filterData() on fullCov to reduce the required
## memory before using regionMatrix(). This can be useful when mc.cores > 1
filteredCov <- lapply(fullCov, filterData,
    returnMean = TRUE, filter = "mean",
    cutoff = 5, totalMapped = libSize, targetSize = 4e4
)
regionMat2 <- regionMatrix(filteredCov,
    maxRegionGap = 10L,
    maxClusterGap = 300L, L = 36, runFilter = FALSE
)

## End(Not run)

## regionMatrix() can work with multiple chrs as shown below.
fullCov2 <- list("chr21" = DataFrame(x, y, z), "chr22" = DataFrame(x, y, z))
regionMat2 <- regionMatrix(
    fullCov = fullCov2, maxRegionGap = 10L,
    maxClusterGap = 300L, L = 36, totalMapped = libSize, targetSize = 4e4
)

## Combine results from multiple chromosomes
library("GenomicRanges")

## First extract the data
regs <- unlist(GRangesList(lapply(regionMat2, "[[", "regions")))
covMat <- do.call(rbind, lapply(regionMat2, "[[", "coverageMatrix"))
covBp <- do.call(c, lapply(regionMat2, "[[", "bpCoverage"))
## Force the names to match
names(regs) <- rownames(covMat) <- names(covBp) <- seq_len(length(regs))
## Combine into a list (not really needed)
mergedRegionMat <- list(
    "regions" = regs, "coverageMatrix" = covMat,
    "bpCoverage" = covBp
)
```

`sampleDepth` *Calculate adjustments for library size*

Description

For a given data set calculate the per-sample coverage adjustments. Hector Corrada's group proposed calculating the sum of the coverage for genes below a given sample quantile. In this function, we calculate the sample quantiles of interest by sample, and then the sum of the coverage for bases below or equal to quantiles of interest. The resulting values are transformed log2(x

- scalefac)

to avoid very large numbers that could potentially affect the stability of the F-statistics calculation. The sample coverage adjustments are then used in makeModels for constructing the null and alternative models.

Usage

```
sampleDepth(collapsedFull, probs = c(0.5, 1), scalefac = 32, ...)
```

Arguments

collapsedFull	The full coverage data collapsed by sample as produced by collapseFullCoverage.
probs	Number(s) between 0 and 1 representing the quantile(s) of interest. For example, 0.5 is the median.
scalefac	Number added to the sample coverage adjustments before the log2 transformation.
...	Arguments passed to other methods and/or advanced arguments. Advanced arguments: **verbose** If TRUE basic status updates will be printed along the way. **nonzero** If TRUE only the nonzero counts are used to calculate the library size adjustment. Default: TRUE. **center** If TRUE the sample coverage adjustements are centered. In some cases, this could be helpful for interpretation purposes. Default: FALSE.

Value

A matrix (vector of `length(probs) == 1`) with the library size depth adjustments per sample to be used in makeModels. The number of rows corresponds to the number of quantiles used for the sample adjustments.

Examples

```
## Collapse the coverage information
collapsedFull <- collapseFullCoverage(list(genomeData$coverage),
    verbose = TRUE
)

## Calculate library size adjustments
sampleDepths <- sampleDepth(collapsedFull, probs = c(0.5, 1), verbose = TRUE)
sampleDepths
```
