# Package 'Wrench'

November 6, 2025

```
Depends R (>= 3.5.0)
Type Package
Title Wrench normalization for sparse count data
Version 1.29.0
Description Wrench is a package for normalization sparse genomic count data, like that aris-
      ing from 16s metagenomic surveys.
Imports limma, matrixStats, locfit, stats, graphics
License Artistic-2.0
LazyData TRUE
RoxygenNote 6.1.0
Suggests knitr, rmarkdown, metagenomeSeq, DESeq2, edgeR
VignetteBuilder knitr
biocViews Normalization, Sequencing, Software

.estimSummary

Obtain robust means. .

# Description

Obtain robust means. .

# Usage

```
.estimSummary(res, estim.type = "s2.w.mean", ...)
```

# Arguments

res result structure of wrench estim.type estimator type

... other parameters

### Value

a chosen summary statistic

.getCondLogWeights 3

.getCondLogWeights

Log Postive-conditional weight computations for wrench estimators.

# **Description**

Log Postive-conditional weight computations for wrench estimators.

# Usage

```
.getCondLogWeights(res)
```

#### **Arguments**

res

result structure of wrench

#### Value

inverse variance weights when using positive conditional models.

.getCondWeights

Postive-conditional weight computations for wrench estimators.

# Description

Postive-conditional weight computations for wrench estimators.

# Usage

```
.getCondWeights(res)
```

# **Arguments**

res

result structure of wrench

#### Value

positive conditional weights for each sample

.getMargWeights

.getHurdle	Obtains logistic fits for presence/absence and fitted probabilities of a zero occurring.

# **Description**

This function is used to derive weights for feature-wise compositional estimates. Our (default) intention is to derive these based on average occurrences across the dataset, as just a function of sample depth, and not with particular relevance to groups.

# Usage

```
.getHurdle(mat, hdesign = model.matrix(~-1 + log(colSums(mat))),
    pres.abs.mod = TRUE, thresh = FALSE, thresh.val = 1e-08, ...)
```

# Arguments

mat	count matrix
hdesign	design matrix for the logistic; the default is usually sufficient.
pres.abs.mod	TRUE if glm regression is for presence or absence. FALSE if glm regression is for counts.
thresh	TRUE if numerically one/zero probability occurrences must be thresholded
thresh.val	if thresh is true, the numerically one/zero probability occurrences is thresholded to this value
	other parameters

#### Value

A list with components:

- pi0.fit list with feature-wise glm.fit objects
- pi0 matrix with fitted probabilities

.getMargWeights	Marginal weight computations for wrench estimators.	

# **Description**

Marginal weight computations for wrench estimators.

# Usage

```
.getMargWeights(res, z.adj, ...)
```

.getReference 5

# **Arguments**

res	result structure of wrench
z.adj	TRUE if the result structure was generated with wrench with z.adj set to TRUE.
	other parameters

# Value

inverse marginal variances for robust mean computing

.getReference

This function generates the reference.

# Description

This function generates the reference.

# Usage

```
.getReference(mat, ref.est = "sw.means", ...)
```

# Arguments

mat count matrix; rows are features and columns are samples ref.est reference estimate method ... other parameters

#### Value

the reference to be used for normalization

.gets2

Obtain variances of logged counts.

# Description

Obtain variances of logged counts.

# Usage

```
.gets2(mat, design = model.matrix(mat[1, ] ~ 1), plot = FALSE,
  ebs2 = TRUE, smoothed = FALSE, ...)
```

.getWeightedMean

### **Arguments**

mat count matrix; rows are features and columns are samples.

design model matrix for the count matrix

plot if the mean-variance trend function (the same as that of voom) needs to be plot.

ebs2 if regularization of variances needs to be performed.

smoothed TRUE if all the variance estimates must be based on the mean-variance trend

function.

... other parameters

# Value

a vector with variance estimates for logged feature-wise counts.

.getWeightedMean

Get weighted means for matrix

# **Description**

Get weighted means for matrix

# Usage

```
.getWeightedMean(mat, w = rep(1, nrow(mat)))
```

# **Arguments**

mat input matrix w weights

# Value

column-wise weighted means.

.getWeightedMedian 7

getW	loio	h+a	dMa	dian
.getw	IE 1 9	nte	ame	11 an

Get weighted median for matrix

#### **Description**

Get weighted median for matrix

#### Usage

```
.getWeightedMedian(mat, w = rep(1, nrow(mat)))
```

# Arguments

```
mat input matrix w weights
```

#### Value

column-wise weighted means.

wrench

Normalization for sparse, under-sampled count data.

# Description

Obtain normalization factors for sparse, under-sampled count data that often arise with metagenomic count data.

# Usage

```
wrench(mat, condition, etype = "w.marg.mean", ebcf = TRUE,
  z.adj = FALSE, phi.adj = TRUE, detrend = FALSE, ...)
```

# **Arguments**

mat

count matrix; rows are features and columns are samples

condition

a vector with group information on the samples

etype

weighting strategy with the following options:

- hurdle.w.mean, the W1 estimator in manuscript.
- w.marg.mean, the W2 estimator in manuscript. These are appropriately computed depending on whether z.adj=TRUE (see below)
- s2.w.mean, weight by inverse of feature-variances of logged count data.

ebcf

TRUE if empirical bayes regularization of ratios needs to be performed. Default recommended.

8 wrench

z.adj	TRUE if the feature-wise ratios need to be adjusted by hurdle probabilities (arises when taking marginal expectation). Default recommended.
phi.adj	TRUE if estimates need to be adjusted for variance terms (arises when considering positive-part expectations). Default recommended.
detrend	FALSE if any linear dependence between sample-depth and compositional factors needs to be removed. (setting this to TRUE reduces variation in compositional factors and can improve accuracy, but requires an extra assumption that no linear dependence between compositional factors and sample depth is present in samples).
	other parameters

#### Value

#### a list with components:

- nf, *normalization factors* for samples passed. Samples with zero total counts are removed from output.
- ccf, compositional correction factors. Samples with zero total counts are removed from output.
- others, a list with results from intermediate computations.
  - gref, reference chosen.
  - design, design matrix used for computation of positive-part parameters.
  - s2, feature-wise variances of logged count data.
  - r, (regularized) ratios of feature-wise proportions.
  - radj, adjustments made to the regularized ratios based on z.adj and phi.adj settings.

#### Author(s)

#### M. Senthil Kumar

# **Examples**

```
#Obtain counts matrix and some group information
require(metagenomeSeq)
data(mouseData)
cntsMatrix <- MRcounts(mouseData)
group <- pData(mouseData)$diet
#Running wrench with defaults
W <- wrench( cntsMatrix, condition=group )
compositionalFactors <- W$ccf
normalizationFactors <- W$nf

#Introducing the above normalization factors for the most
# commonly used tools is shown below.

#If using metagenomeSeq
normalizedObject <- mouseData
normFactors(normalizedObject) <- normalizationFactors</pre>
```
