

Package ‘Rcell’

June 4, 2015

Type Package

Version 1.3-2

Date 2015-06-04

Title Microscopy Based Cytometry Data Analysis Package

Author Alan Bush <abush@fbmc.fcen.uba.ar>

Maintainer Alan Bush <abush@fbmc.fcen.uba.ar>

Depends R (>= 2.15.0), proto, plyr (>= 1.8), reshape, ggplot2 (>= 0.9.3), grid

Imports stats, digest

Suggests Hmisc, EBImage (>= 4.0.0), RcellData (>= 1.3.0)

Description Analyze microscopy based cytometry datasets created with 'Cell-ID'. It includes functions for manipulating and plotting the data. It can also create automatic image montages of cells in a user defined layout.

License GPL-2

Encoding latin1

|---------------|---------------------------------------------------------|

Description

Microscopy based cytometry can produce huge amount of images to be analyzed. Several programs can segment the acquired images and create a dataset with the features of the segmented cells. This package contains functions design to analyze such datasets. It was created to analyze data from Cell-ID (<http://sourceforge.net/projects/cell-id/>), but can be extended to analyze datasets created by other segmentation programs.

For a introduction read the 'Getting Started with Rcell' vignette
vignette(Rcell)

To learn how to create complex plots read
vignette(cplot)

To see how to create layouts of cell's images read
`vignette(cimage)`

To learn how to normalize and manipulate your data read
`vignette(transform)`

To read a description of Cell-ID's variables and features
`vignette(Cell-ID-vars)`

Loading Cell-ID Data in R

Once you have processed the images with Cell-ID you will have to analyse the output dataset. The first thing you will have to do is load your data into R.

`load.cellID.data`: this function searches a specified directory (the working directory by default) for folders that match a customizable pattern, usually PositionXX where XX is the position number. The function loads these files and generates a suitable data structure. It returns an object of class `cell.data` that contains all the required information for the analysis. All the functions included in the package operate over this object, and its components should not be modified directly, but through the provided functions.

Quality Control and Filtering Cells

The algorithm used by Cell-ID to find the cells can occasionally make mistakes in the assignment of the cell boundaries and produce badly found and spurious cells (i.e. image structures erroneously scored as cells). Furthermore, the program does not discriminate out of focus and dead cells.

Normally you will want to get rid of all the spurious, badly found, out of focus and dead cells (referred collectively as 'bad' cells), which would constitute a 'quality control' of the data. The R package contains some functions to aid in this process.

`QC.filter`: applies quality control filters over the data. The purpose of this function is to eliminate from the dataset 'bad' cells. You should not use this function to differentiate sub-groups of 'good' cells. This function treats a cell in different time points independently (i.e. it operates on registers of the dataset). To eliminate cells that are not scored in all the time frames, call `update.n.tot` and then filter by `n.tot`. Filters can be undone by `QC.undo`, or reset by `QC.reset`. Use `summary.cell.data` to see a summary of the applied filters.

Plotting the Data

For plotting the data you can use the package plotting functions `cplot` and `cplotmeans`, which are wrappers over the `ggplot2` package functions.

Image Layout

To create image layouts (or montages) of your cells use the `cimage` functions.

Data Manipulation

Some common manipulations you can apply over a `cell.data` object are subsetting (`subset.cell.data`) which returns a `cell.data` object, extraction (`[].cell.data`) and aggregation (`aggregate.cell.data`) which return a `data.frame`. You can also create new variables from existing ones. This can be done to save typing, or to normalize your data. To this end you can use the `transform.cell.data` and `transform.by.cell.data` functions.

aggregate

Compute Summary Statistics of Cell Data Subsets

Description

Splits the data into subsets, computes summary statistics for each, and returns the result in a data frame

Usage

```
## S3 method for class cell.data
aggregate(x, form.by, ..., FUN=mean, subset=TRUE, select=NULL
,exclude=NULL, QC.filter=TRUE)

aggregateBy(x, .by, ...)

## S3 method for class cell.data
aggregateBy(x, .by, select, ..., FUN=mean, subset=TRUE, exclude=NULL, QC.filter=TRUE)

## S3 method for class data.frame
aggregateBy(x, .by, select="all", ..., FUN=mean, subset=NULL, exclude=NULL)

## Default S3 method:
aggregateBy(x, .by, select="all", ..., FUN=mean, subset=NULL, exclude=NULL)
```

Arguments

| | |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x | cell.data object |
| form.by | either a formula or variables to split data frame by, as quoted variables or character vector |
| .by | variables to split data frame by, as quoted variables or character vector |
| ... | further arguments passed to or used by methods |
| FUN | a function to compute the summary statistics which can be applied to all data subsets |
| subset | a boolean vector of length equal to the number of rows of the dataset, or a conditional statement using the datasets variable, that specifies which registers should be included |

| | |
|-----------|------------------------------------------------------------------------------------------|
| select | character vector defining variables names to be included in the returned data.frame |
| exclude | character vector defining variables names to be excluded from the returned data.frame |
| QC.filter | a boolean value indicating if the quality control filter should be applied over the data |

Details

`aggregate` is a generic function. This version applies to `cell.data` objects. Two notations are allowed. If the second argument `form.by` is a formula it should be of the form `cbind(measure.var1,measure.var2)~group`. If the second argument `form.by` are quoted variables or a character vector with variable names, these variables are taken as `group.vars` to split the dataset. The measure variables over which to apply FUN should be selected using the `select` and `exclude` arguments.

`aggregateBy` works as `aggregate`, but forces the use of quoted variables (or variable names) to define the groups by which the dataset is going to be split. This function also has a implementation for data frames. `aggregateBy` calls `flatten` before returning the data frame.

Value

a data frame with columns corresponding to the grouping variables followed by aggregated columns of the measure variables.

[aggregate](#)

Examples

```
if(require(RcellData)){
  #load example dataset
  data(ACL394filtered)

  #aggregate by pos and calculate mean f.tot.y
  aggregate(X,.(pos),select="f.tot.y")

  #do the same aggregation using the formula notation
  aggregate(X,f.tot.y~pos)

  #aggregate by pos and t.frame
  aggregate(X,.(pos,t.frame),select="f.tot.y")
  aggregate(X,f.tot.y~pos+t.frame) #formula notation

  #aggregate several variables
  aggregate(X,.(pos),select="f.tot.?", # using wildcard pattern matching
  aggregate(X,cbind(f.tot.y,f.tot.c)~pos) #formula notation

  #subset before aggregating
  aggregate(X,.(pos),select="f.tot.y",subset=t.frame==13)

  #calculate the median instead of the mean
  aggregate(X,.(pos),select="f.tot.y",FUN=median)
```

```

#dont apply the QC filter to the daset before aggregation
aggregate(X,.(pos),select="f.tot.y",QC.filter=FALSE)

#use aggregateBy on a cell.data object
(agg<-aggregateBy(X,.(pos,AF.nM,t.frame),select="f.tot.y"))

#use aggregateBy on a data.frame, calculate mean and sd among position means
aggregateBy(agg,.(AF.nM,t.frame),select="f.tot.y",FUN=funstofun(mean,sd))

}

```

as.cell.data

Coerce to Cell Data

Description

Coerces a list or data.frame to a cell.data object

Usage

```

as.cell.data(X,...)

## S3 method for class list
as.cell.data(X,path.images=NULL,...)

is.cell.data(X)

```

Arguments

| | |
|-------------|------------------------------------------------------|
| X | list to be coerced to (or test for) cell.data object |
| path.images | string containing path to the image files |
| ... | additional arguments to be passed to or from methods |

Details

as.cell.data coerces objects to class cell.data. If a list is coerced, it is expected to have components 'data', 'bf.fl.mapping' and others. It is specially usefull to coerce data loaded with previous versions of Rcell. is.cell.data test if a object inherits from class cell.data

path is used to update the path of the image files.

Value

a cell.data object

Author(s)

Alan Bush

See Also[load.cellID.data](#)**Examples**

```

if(require(RcellData)){

  #load example dataset
  data(ACL394)

  #transforming dataset to list
  Xlist<-as.list(X);class(Xlist)<-"list";

  #re-coerce to cell.data
  Y<-as.cell.data(Xlist)
}

```

as.data.frame

*Coerce to a Data Frame***Description**

Function for extracting a (subset) data.frame from a cell.data object

Usage

```

## S3 method for class cell.data
as.data.frame(x,row.names=NULL,optional=FALSE,...,subset=TRUE
  ,select=NULL,exclude=NULL,QC.filter=TRUE,na.rm=FALSE)

## S3 method for class cell.data
x[[subset=TRUE,select=NULL,exclude=NULL,QC.filter=TRUE,na.rm=TRUE,...]]

cdata(x,subset=TRUE,select=NULL,exclude=NULL,QC.filter=TRUE,na.rm=TRUE,...)

```

Arguments

| | |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x | cell.data object |
| subset | a boolean vector of length equal to the number of rows of the dataset, or a conditional statement using the dataset?s variable, which specifies which registers should be included in the returned data.frame |
| select | character vector defining variables names to be included in the returned data.frame |
| exclude | character vector defining variables names to be excluded from the returned data.frame |
| QC.filter | a boolean value indicating if the quality control filter should be applied over the data |
| na.rm | boolean indicating if registers with NA should be removed from the data.frame |
| ... | further arguments passed to or used by methods |
| row.names | further arguments passed to or used by methods |
| optional | further arguments passed to or used by methods |

Details

`as.data.frame.cell.data` coerces a `cell.data` object to a `data.frame`, subsetting it as defined by the other arguments. This function will be called when the generic function `as.data.frame` is applied over a `cell.data` object.

The extract (`'[[]'`) operator is an alias to this function.

`select` and `exclude` can be used to choose which variables should be included in the returned `data.frame`. Wildcard patterns (e.g. `'f.*.y'`) and keywords (e.g. `'all'`, `'id.vars'`, `'YFP'`, etc.) can be used as components of these arguments. Use `summary.cell.data` to see available variables and keywords. Variable names starting with `'-'` in `select` will be excluded from the `data.frame`.

Value

A `data.frame`, subset as specified by the functions arguments.

Examples

```
if(require(RcellData)){  
  
  #load example dataset  
  data(ACL394)  
  
  #extract the dataset to a data.frame  
  df<-as.data.frame(X)  
  df<-X[[[]]]  
  
  #extract a subset of the data.frame  
  df<-X[[t.frame==13,]]  
  
  #extract a selected group of variables  
  df<-X[[,c("id.vars","f.tot.?", "a.tot")]]  
  #note the use of keywords, patterns and variable names  
  
  #extract the dataset without applying the QC filter  
  df<-cdata(X,QC.filter=FALSE)  
}
```

cell.data

Cell Data Object

Description

cell.data object description

Details

cell.data objects created by `load.cellID.data` and manipulated by the functions of the package. They are list with class 'cell.data' and contain the following elements

data main data.frame containing all the variables created by Cell-ID, plus additional variables created in R. To see a full description of Cell-ID's variables read the 'Cell-ID-vars' vignette (`vignette(Cell-ID-vars)`). It also contains the special QC variable, that contains the Quality Control filter created by `QC.filter`.

QC.history list containing the description of the different filters applied with `QC.filter`

subset.history list containing the description of the different subsets applied with `subset.cell.data`

transform list containing the description of the variables created with `transform.cell.data` or `transformBy.cell.data`

channels data.frame containing the names and postfix of the available fluorescence channels

variables list containing all the available variable names. The names of the items of the list work as a keyword. Each item contains a character vector with variable names (elements of data). Example of keywords (`$variables` elements) are 'id.vars', 'morpho', 'fluor', 'all', 'transformed', 'YFP', etc.

images data.frame containing information regarding the images run by Cell-ID.

software character describing the segmentation software used

load.date character containing the date in which the dataset was loaded to R.

cell.image

Get Cells Images

Description

Retrieves the images from single cells in an cell.image object

Usage

```
get.cell.image(X,...)

## S3 method for class cell.data
get.cell.image(X,subset=NULL,channel.subset=NULL,channel=NULL
,time.course=TRUE,group=NULL,na.rm=TRUE,N=7,select=NULL,exclude=NULL
,QC.filter=TRUE,box.size=20,...)

## S3 method for class data.frame
get.cell.image(X,box.size=20,contained.box=FALSE,bg.col=0,...)

## Default S3 method:
get.cell.image(X,box.size=20,...)

## S3 method for class cell.image
summary(object,...)
```

```
## S3 method for class summary.cell.image
print(x,...)

## S3 method for class cell.image
print(x,nx=ceiling(sqrt(length(x))),...)

img.desc(X)

img.desc(X)<- value

is.cell.image(X)
```

Arguments

| | |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X | cell.data object or data.frame that specifies the images |
| subset | logical expression indicating elements or rows to keep. Don't specify channel here. |
| channel.subset | logical expression to specify which image to retrieve with channel and t.frame variables. |
| channel | character vector of channels to retrieve. If specified, defines the order of the channels. |
| time.course | boolean indicating if the desired image montage is a time course (i.e. several images for the same cell) |
| group | character vector or quoted names of variables who's interaction define the groups from which select N random cells. |
| na.rm | boolean indicating if NAs should be removed. |
| N | Number of random cells to select from each group. If NULL all cells are selected |
| select | character vector defining variables names to be included in the returned cell.image object |
| exclude | character vector defining variables names to be excluded from the returned cell.image object |
| QC.filter | a boolean value indicating if the quality control filter should be applied over the data |
| box.size | size in pixels of the image containing the cells. This specifies the 'radius', i.e. the image will be a square of length 2*box.size+1 |
| ... | further arguments for methods |
| contained.box | boolean indicating if the XY position of the box should be corrected to be contained in the original image. Relevant for cells close to the image border. If FALSE the part of the box outside the original image will be filled with bg.col |
| bg.col | color to be used for the background of the images |
| object | cell.image object to summarize |
| x | object to print |
| nx | number of columns in the image tile |
| value | a data.frame to use as image description database |

Details

`get.cell.image` is a generic method that returns a `cell.image` object.

If `get.cell.image` first argument is a `data.frame`, it should contain the columns `path`, `image`, `xpos` and `ypos`.

If the first argument when calling `get.cell.image` is a `cell.data` object, further arguments specify which images will be selected. The `subset` arguments filters the dataset as in other functions. If some variables are specified in `group`, the data is split in groups defined by these variables, and from each group `N` cells are selected at random. The `channel` argument specifies which channels to show. If a more complex image selection is required, you can use the `channel.subset` argument. For example if you want to see the BF only for the first `t.frame`, and then only the YFP channel, you can use `channel.subset=channel==YFP|(t.frame==0&channel==BF)`

`img.desc` returns a `data.frame` describing each image of the `cell.image` object

Value

a `cell.image` object. This object is basically a list whose elements are the cropped images of single cells. It has a attribute named `'img.desc'` that is a `data.frame` with the image index (`img.index`) and description of all the components of the objects.

`EImage`

Examples

```
if(interactive() & require(EImage,quietly=TRUE) & require(RcellData)){

  #load example dataset
  data(ACL394filtered)

  #select N=3 cells images from each pos (group),
  #from the first t.frame and pos 1,8,15,22,29.
  ci<-get.cell.image(X,subset=match(pos,c(1,8,15,22,29),nomatch=0)>0&t.frame==11,
    group=(pos),N=3,channel=c(BF.out,YFP))
  print(ci) #print the cells images
  summary(ci) #get a summary of the content
  img.desc(ci) #get the image description data.frame

  #select the first 4 t.frames for YFP, and the first t.frame for BF
  ci<-get.cell.image(X,subset=pos==29,group=pos,
    channel.subset=channel==YFP|(t.frame==11&channel==BF))
  print(ci)

}
```

cimage

*Images Layout***Description**

Arranges cell's images in a plot

Usage

```
cimage(X,...)

## S3 method for class cell.data
cimage(X, formula=NULL, facets=NULL, QC.filter=TRUE
, time.var=c("*time*", "t.frame", "z.scan", "z.slice"), time.course=NULL
, select=NULL, exclude=NULL, normalize.group="channel", invert.lut=FALSE
, N=NULL,...)

## S3 method for class cell.image
cimage(X, formula=NULL, subset=NULL, facets=NULL
, scales="fixed", allow.expressions=FALSE
, nx=NULL, ny=NULL, facets.nx=NULL, facets.ny=NULL
, bg.col="white", border=1, facets.border=1, rev.y=TRUE
, font.size=14, font.col="black", display=interactive(),...)

## Default S3 method:
cimage(X,...)
```

Arguments

| | |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| X | cell.data or cell.image object to plot |
| formula | formula of the form 'var1+var2~var3' specifying how the images are to be ordered. See details. |
| facets | formula of the form 'var1+var2~var3' specifying how to facet the plot. See details. |
| time.var | variables that indicate time and should be excluded from the grouping variables. See get.cell.image |
| time.course | boolean indicating if the image layout represents a time course and several images of the same cell at different times are expected |
| select | character vector defining further variables that are required for the plot |
| exclude | character vector defining variable names to be excluded |
| normalize.group | variable names that define groups of images that should be normalized together |
| scales | either 'none', 'fixed' or 'free' axis for each facet |
| allow.expressions | allow expressions in formulas, set to TRUE when called from cimage.cell.data |
| nx | number of columns of images within each facet. Used with formula '~var1' or 'var1~.' |

| | |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ny</code> | number of rows of images within each facet. Used with formulas <code>'~var1'</code> or <code>'var1~.'</code> |
| <code>facets.nx</code> | number of columns of facets. Used with facets <code>'~var1'</code> or <code>'var1~.'</code> |
| <code>facets.ny</code> | number of rows of facets. Used with facets <code>'~var1'</code> or <code>'var1~.'</code> |
| <code>bg.col</code> | The background color of the plot |
| <code>border</code> | the width in pixels of the border between images |
| <code>facets.border</code> | the width in pixels of the border between facets |
| <code>rev.y</code> | boolean indicating if the y axis should be reversed |
| <code>font.size</code> | The size of the font to use, in pixels |
| <code>font.col</code> | The color of the font to use |
| <code>display</code> | boolean indicating if the created image should be displayed |
| <code>QC.filter</code> | a boolean value indicating if the quality control filter should be applied over the data |
| <code>invert.lut</code> | boolean indicating if Look Up Table should be inverted |
| <code>N</code> | Number of random cells to select from each group. If NA or 'all', all cells are selected. |
| <code>subset</code> | logical expression indicating elements or rows to keep. Don't specify channel here |
| <code>...</code> | further arguments for methods. <code>cimage</code> calls <code>get.cell.image</code> , so all the arguments of this function are available. |

Details

| | |
|-----------------------------|----------------------------------------------------------------------------------------------------------------|
| <code>channel.subset</code> | logical expression to specify which image to retrieve with channel and t.frame variables |
| <code>channel</code> | character vector of channels to retrieve. If specified, defines the order of the channels |
| <code>box.size</code> | size in pixels of the image containing the cells. This specifies the 'radius', i.e. the image will be a square |
| <code>contained.box</code> | boolean indicating if the XY position of the box should be corrected to be contained in the original image |
| <code>bg.col</code> | color to be used for the background of the images |

Read the `cimage` vignette for a tutorial on how to use this function: `vignette('cimage')`

`cimage` is a generic method that returns a 'Image' object, from `EImage` package.

If `cimage`'s first argument is a `cell.data` object, it first calls `get.cell.image` and then the `cimage` method for `cell.image` objects. This function arranges the images of single cells according to the formula and facets arguments, and adds appropriated axis to the image.

For example, `formula=channel~t.frame`, will arrange different channels as rows and `t.frame` as columns. You can use several variables per term, for example `formula=channel~pos+t.frame` will arrange the columns first by position, and within each position by `t.frame`. The variable to the right varies faster than the one to the left. If only the right term of the formula is defined, as in `formula=~t.frame`, the images are 'wrapped' around, attempting to create a square plot. `nx` and `ny` can be used to define the number of columns or rows respectively. The special keyword 'cell' can be used to indicate the samples within a group, for example `formula=cell~t.frame`. The facets argument works in a similar way.

Value

The function returns an invisible 'Image' object of the EImage package. Use `display` to render the image or `writeImage` to save it. You can also use `plot` to print to the active device and `img.desc` to retrieve the description of each cell.

Examples

```
if(interactive() & require(EImage, quietly=TRUE) & require(RcellData)){

#load example dataset
data(ACL394filtered)

#display timecourse strip of cell 5 of pos 29, channels BF and YFP
cimage(X, channel~t.frame, subset=pos==29 & cellID==5, channel=c(BF, YFP))

#display 7 cells (default value for N) of pos 29
cimage(X, cell+channel~t.frame, subset=pos==29, channel=c(BF, YFP))

#display 3 cells from each pos in a different facet
cimage(X, channel~cell, facets=~pos, channel=c(BF.out, YFP), N=3,
subset=t.frame==11 & match(pos, c(1, 8, 15, 22, 29), nomatch=0) > 0)

#select one BF and many YFP images
cimage(X, cell~channel+t.frame, subset=pos==29, N=3,
channel.subset=channel==YFP | (channel==BF.out & t.frame==11))

#make a movie!
cimage(X, ~cell|t.frame, subset=pos==29, channel=YFP, N=9)

}
```

conform

Conform a Data Frame

Description

conforms the structure of a `data.frame` to that of another

Usage

```
conform(df, to)
```

Arguments

df data.frame to be conformed
to data.frame to use as template (columns order)

Details

this function is useful do rbind between data frames that have different columns, or columns in different order.

Value

a data frame conformed to the template

Author(s)

Alan Bush

Examples

```
#creating example data frames
df1<-data.frame(a=1:4,b=5:8)
df2<-data.frame(b=9:14)
df3<-data.frame(b=9:14,a=20:25)

#using conform
conform(df2,to=df1)
conform(df3,to=df1)

#using conform with rbind
rbind(df1,conform(df2,to=df1))
rbind(df1,conform(df3,to=df1))
```

cplot

Plotting Cell Data Objects

Description

Plotting functions for cell.data objects. These functions are wrappers over the functions of ggplot2 package.

Usage

```
cplot(X=NULL, x=NULL, subset = NULL, y=NULL, z=NULL, ...
, facets = NULL, margins=FALSE, geom = "auto"
, stat=list(NULL), position=list(NULL), log = "", as.factor="as.factor"
, xlim = c(NA, NA), ylim = c(NA, NA), xzoom = c(NA,NA), yzoom = c(NA,NA)
, xlab = deparse(substitute(x)), ylab = deparse(substitute(y)), asp = NA
, select = NULL, exclude = NULL, na.rm = TRUE, QC.filter = TRUE
, main = NULL, add = FALSE, layer = FALSE)
```

```

clayer(...,geom="auto")

cplotmeans(...,geom=c("point","errorbar","line"))

clayermeans(...,geom=c("point","errorbar","line"))

cplotmedian(...,geom=c("point","errorbar","line"))

clayermedian(...,geom=c("point","errorbar","line"))

## S3 method for class cell.data
plot(x,y,...)

```

Arguments

| | |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X | cell.data object |
| x | either a variable symbol or expression, or a formula of the form $y \sim x$ or $\sim x$ |
| subset | a boolean vector of length equal to the number of rows of the dataset, or a conditional statement using the dataset's variable, which specifies which registers should be included in the plot |
| y | a variable symbol or expression to be plot in the y axis. Ignored if x is a formula. A vector of symbols is allowed |
| z | a variable symbol specifying the "z" aesthetic mapping |
| ... | other arguments passed on to the geom functions |
| facets | faceting formula to use |
| margins | whether or not margins will be displayed |
| geom | geom to use (can be a vector of multiple names) |
| stat | statistic to use (can be a vector of multiple names) |
| position | position adjustment to use (can be a vector of multiple names) |
| log | which variables to log transform ("x", "y", or "xy") |
| as.factor | variable names (wildcard pattern or keyword) to be treated as factors |
| xlim | limits for x axis $c(\min, \max)$ (filters the x variable BEFORE applying the stat transformation) |
| ylim | limits for y axis $c(\min, \max)$ (filters the y variable BEFORE applying the stat transformation) |
| xzoom | zoom range for x axis $c(\min, \max)$ (resizes the plotting region AFTER the stat transformation) |
| yzoom | zoom range for y axis $c(\min, \max)$ (resizes the plotting region AFTER the stat transformation) |
| xlab | character vector or expression for x axis label |
| ylab | character vector or expression for y axis label |
| asp | the y/x aspect ratio |
| select | character vector defining variables names to be included in the returned ggplot object, beside the ones required for the plot |
| exclude | character vector defining variables names to be excluded from the returned ggplot object |

| | |
|------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>na.rm</code> | boolean indicating if registers with NA should be removed from the <code>data.frame</code> |
| <code>QC.filter</code> | a boolean value indicating if the quality control filter should be applied over the data before plotting |
| <code>main</code> | character vector or expression for plot title |
| <code>add</code> | the plot is added as a layer to the last plot (returned by <code>last_plot</code>) |
| <code>layer</code> | boolean. If TRUE a layer is returned instead of a new <code>ggplot</code> object. Mutually exclusive with <code>add</code> |

Details

Read the `cplot` vignette for a tutorial on how to use this function: `vignette('cplot')`

`cplot` is a wrapper over the functions of `ggplot2` package from Hadley Wickham. It is based on `qplot` and keeps many of its arguments. The main differences between `cplot` and `qplot` are the following:

- `cplot`'s first argument is a `cell.data` object (or a `data.frame`)
- the 'x' and 'y' aesthetic mapping can be specified by a formula in `cplot`
- a vector of variables can be specified for 'y' aesthetic mapping. This produces a data restructuring and sets the color aesthetic to variable
- variables selected by `as.factor`s are coerced to factors before plotting
- the plotting region can be easily specified with `xzoom` and `yzoom`. Useful when `stat='summary'`.
- a subset of the dataset can be performed before plotting
- only the required variables for the plot are included in the `ggplot` object, thus reducing the memory space it requires. Additional variables can be included with the `select` and `exclude` arguments.
- if a logical QC variable is present in the dataset, it is used to filter it before plotting
- unused levels of factors can be drop with `droplevels`
- the specified plot can be returned as a layer to add to other plots with the '+' operator

`clayer` is a wrapper for `cplot` with `layer=TRUE`. This function returns a layer that can be added to other `ggplot` objects with the '+' operator.

`cplotmeans` (alias `cplotmean`) is a wrapper over `cplot` with `stat='summary'` and `fun.data='mean_cl_normal'`. This function plots the mean and confidence limits for the mean of the data, grouped by levels of the x variable. The default confidence interval is of 95%, and can be modified with the `conf.int` argument (passed to `smean.cl.normal`).

`clayermeans` (alias `clayermean`) is a wrapper over `cplot` with `stat='summary'`, `fun.data='mean_cl_normal'` and `layer=TRUE`.

`cplotmedian` (and `clayermedian`) is a wrapper over `cplot` with `stat='summary'`, `fun.data='median_hilow'` and `layer=FALSE` (TRUE).

`plot.cell.data` is a wrapper over `cplot`. It only accepts formula notation for the 'x' and 'y' aesthetics. It can be called by `plot` over a `cell.data` object.

Value

a `ggplot` object or a list specifying plots layers

Author(s)

Alan Bush

draw.img

Draw on a Image

Description

funcionts for modifying EBImage images

Usage

```
drawCross(img, x, y, size=2, col=0.75, z=1)
```

```
drawLine(img, x1, y1, x2, y2, col=0.75, z = 1)
```

```
drawText(img, labels, x=NULL, y=NULL, adj=c(0,0), reuseLabels=TRUE, col=NULL)
```

Arguments

| | |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| img | EImage Image to modify |
| x | vector of x positions to draw |
| y | vector of y positions to draw |
| x1 | vector of x1 positions to draw |
| y1 | vector of y1 positions to draw |
| x2 | vector of x2 positions to draw |
| y2 | vector of y2 positions to draw |
| labels | character vector of labels |
| adj | one or two values in [0, 1] which specify the x (and optionally y) adjustment of the labels. On most devices values outside that interval will also work. |
| col | color of the object |
| size | size of the cross |
| reuseLabels | boolean indicating if labels created in previous calls should be reused |
| z | image layer in which to draw |

Details

drawCross, drawLine and drawLabel draw on EImage images, at the specified x y positions.

Value

a EImage image

 flatten

Flatten a Data Frame

Description

converts matrix elements of data frames into columns

Usage

```

flatten(df,...)

## S3 method for class data.frame
flatten(df,...)

```

Arguments

| | |
|-----|------------------------------------------------|
| df | data.frame to be flattened |
| ... | further arguments passed to or used by methods |

Details

this function is useful to flatten data frames obtained by aggregate when using `smean.cl.normal` and other functions from `Hmisc`.

Value

a data frame

Examples

```

if(require(Hmisc)&require(RcellData)){
  #load example dataset
  data(ACL394)
  agg<-aggregate(X,f.tot.y~pos,subset=t.frame==0,FUN=smean.cl.normal)
  str(agg)
  agg<-flatten(agg)
  str(agg)
}

```

| | |
|----------------|-----------------------|
| ggplot2.themes | <i>ggplot2 themes</i> |
|----------------|-----------------------|

Description

Themes for ggplot2 graphics

Usage

```
theme_Rcell()
theme_invisible()
```

Details

I found these functions posted at <https://github.com/hadley/ggplot2/wiki/Themes>. I included them here for convenience.

These functions provide more themes for ggplot2 graphics. They work just as [theme_grey](#) and [theme_bw](#)

Value

A list with theme elements

Examples

```
#creating example dataset
mdf <- data.frame(x <- seq(0, 10), y=rnorm(x),
                  f=factor(rep(letters[1:2], each=3, length=length(x))))

#base plot
p <- qplot(x, y, data=mdf, colour=f, geom=c("line", "point"))

#compare themes
p + theme_grey() + labs(title="theme_grey()")
p + theme_bw() + labs(title="theme_bw()")
p + theme_Rcell() + labs(title="theme_Rcell()")
p + theme_invisible() + labs(title="theme_invisible()")
```

| | |
|------------------|--------------------------|
| load.cellID.data | <i>Load Cell-ID Data</i> |
|------------------|--------------------------|

Description

load.cellID.data searches a specified directory (the working directory by default) for folders that match a customizable pattern, usually PositionXX where XX is the position number. This folders should contain the Cell-ID output files output_all and the output_bf_fl_mapping for each position. The function loads this files and generates a data structure suitable for filtering and plotting. The function returns a cell.data object that contains all the required information for the analysis. All the functions included in the package operate over this object, and its components should not be modified directly, but through the provided functions. Remember to assign the returned value to a variable (e.g. X<-load.cellID.data())

Usage

```
load.cellID.data(pattern="^[Pp]{1}os[:alpha:]*[:digit:]*", path=getwd()
, basename="out", select=NULL, exclude=NULL, load.vars="all", split.image=FALSE)
```

Arguments

| | |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| pattern | regular expression (see regexp) pattern of the position folders, where the images and cell ID output files for each position are stored. |
| path | character containing path from where to apply the pos.pattern to the existing folders. It should point to the folder that contains the PosXX folders. |
| basename | character containing basename of the cell ID output files, should match the -o option passed to cellID when executed. 'out' by default. |
| select | character vector defining variables names to be included in the cell.data object |
| exclude | character vector defining variables names to be excluded of the cell.data object |
| load.vars | character specifying which variables or group of variables of the Cell-ID out_all file should be loaded. |
| split.image | boolean indicating if the images are split and upper cells should be matched to lower cells. Set to TRUE if analyzing a FRET split image experiment. |

Details

reads Cell ID output files (basename)_all in folders that match pattern in path and loads them into a cell.data object.

It searches for the output_all files in folders of the form specified by pattern (regular expression). If the folder has a numeric value in its name that number is taken as the position index (for example pos01 is given the index 1) If no numeric value is found in the folder name, then a ordinal index is assign.

Possible values for load.vars are 'all', 'fl' or 'fluorescence', 'bg' or 'background', 'calc', 'morph' or 'morphological', 'vac' or 'vacuole', 'nucl' or 'nuclear', 'disc'. The group of variables can be specified in either a positive form (i.e. '+fl+bg+morph') or in a negative form (i.e. '-nucl-vac'). Combination of positive and negative form is not allowed. A character vector containing the variables names of the out_all file is also allowed. The selection of variables is done before restructuring, so the variable names should correspond to those of the out_all files. Using this argument can be useful if memory issues arise.

Alternatively select and exclude can be used to subset the dataset. This arguments are applied after the reshaping, so variables names as returned by [summary.cell.data](#) are used. Wildcard patterns (e.g. 'f.*.y') and keywords (e.g. 'all', 'id.vars', 'YFP', etc.) can be used as components of these arguments.

Value

a cell.data object

Note

The restructuring of the data involves arranging the information for each time point of each cell into a single row. In the output of Cell-ID this information appears in several rows, one for each channel. The restructured data 'collapses' this rows into a single one, adding and modifying the column names by appending a channel specific postfix. If split.image is set to TRUE a sub-image identifier is also appended, 'u' for upper and 'l' for lower. When Cell-ID is run, the images

it uses have to be named in a specific way. The first three letters of the image name are used as a channel token, i.e. it identifies the channel. If you have YFP and CFP channels, the images should be named YFP_Position1, YFP_Position2,...,CFP_Position1, CFP_Postion2,... The channel postfix is the shortest unambiguous substring of the channel token in lower case. For example for the tokens 'YFP' and 'CFP', the selected postfix will be 'y' and 'c' respectively.

## End(Not run)
```

merge

Merge a Data Frame to a Cell Data Object

Description

Merges the variables in a data.frame to a cell.data object, using common variables to do the merging

Usage

```
## S3 method for class cell.data
merge(x, y, by=NULL, na.rm=FALSE, add=FALSE, warn=TRUE, pos.offset=NULL, ...)

load.pdata(X, pdata="pdata.txt", by=NULL, path=getwd())
```

Arguments

| | |
|------------|----------------------------------------------------------------------------|
| X | cell.data object |
| x | cell.data object |
| y | a data.frame with at least one common variable with x |
| by | character vector indicating which variables to use for the merging |
| na.rm | should NAs be removed before merging |
| add | boolean indicating if new values should be added to previously merged ones |
| warn | boolean indicating if warnings should be issued |
| pos.offset | position offset used when merging cell.data objects |

| | |
|-------|---------------------------------------------------------------------------------------------------------------------------|
| pdata | either a string with the filename of a tab delimited text file containing the data to be merged, or a data.frame to merge |
| path | string containing the path to the location of the tab delimited file to be loaded |
| ... | additional arguments to be passed to or from methods |

Details

merge is used to add the variables in a data.frame to the cell.data object. It uses common variables to do the merging. The variables can be specified with the by argument.

load.pdata is a wrapper over merge, used to load position information to the cell.data object. By default it looks for a file named 'pdata.txt' in the working directory. This file should have a 'pos' column.

Value

a cell.data object with the merged variables.

Author(s)

Alan Bush

  pdata<-data.frame(pos=1:35,AF.nM=rep(c(1.25,2.5,5,10,20),each=7))

  #merging the data frame with the cell.data object
  X<-merge(X,pdata)

}
```

plot.Image

Plot Image

Description

Plots a EBImage Image to the active device

Usage

```
## S3 method for class Image
plot(x,width=NULL,height=NULL,omi=1,interpolate=FALSE,vp=NULL,...)
```

Arguments

| | |
|-------------|---------------------------------------------------------------------------------------------------------------------------|
| x | EImage of class Image, as returned by <code>cimage</code> |
| width | the width in inches of the device. If width or height are NULL, both are replaced by the dimensions of the active device |
| height | the height in inches of the device. If width or height are NULL, both are replaced by the dimensions of the active device |
| omi | number between 0 and 1. Defines the outer margins. If set to 0.95, 5% of the device in each side will be set as margin |
| interpolate | A logical value indicating whether to linearly interpolate the image |
| vp | A Grid viewport object (or NULL) |
| ... | further arguments for <code>grid.raster</code> |

Details

`plot.Image` is the S3 `plot` method for objects of class 'Image'.

Value

  plot(img)  
  
}
```

QC.filter

*Quality Control Filter***Description**

Create, undo, reset and execute quality control filters

Usage

```
QC.filter(X, filter, subset=NULL)
```

```
QC.undo(X)
```

```
QC.reset(X)
```

```
QC.execute(X)
```

Arguments

| | |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X | the cell.data object as returned by load.cellID.data make sure to save the object when it's returned by the function i.e. do the calls as <code>X=QC.filter(X,...)</code> |
| filter | a boolean vector of length equal to the number of rows of the dataset, or a conditional statement using the datasetYens variable, that specifies which rows pass the quality control (TRUE), and which ones don't (FALSE). |
| subset | a boolean vector of length equal to the number of rows of the dataset, or a conditional statement using the dataset variable, which specifies over which registers filter should be applied. |

Details

QC.filter function filters the cells based on a user define boolean vector filter Such vector can be obtained applying logical operations over the vectors (`fft.stat<0.2`, etc). The purpose of this filter is to eliminate from your dataset spurious, badly found, out of focus and dead cells. This filter is cumulative, meaning that each time one applies a QC.filter function it adds to the previous QC.filter, it does not replaced them. Many functions from the package have a QC.filter argument, that specifies if the created QC filter should be applied to the dataset before the function is executed. The filter treats the same cells in different time points independently. Don't use this function to select subgroups of cells (see [select.cells](#)) [summary.cell.data](#) returns a description of the applied filters.

QC.undo removes the last filter applied. QC.reset eliminates all filters, restoring the cell.data object to its original state. QC.execute permanently eliminates the filtered registers. This is recommended only if you have memory issues.

Value

Returns the cell.data with the specified filter applied.

Note

Some times it is useful to create additional filters to discriminate between cells. Dont use QC.filter for this. You can create a filter with [transform.cell.data](#) and use the subset argument of the function you want to apply.

Author(s)

Alan Bush

See Also[summary.cell.data](#), [transform.cell.data](#), [load.cellID.data](#)**Examples**

```

if(require(RcellData)){

  #load example dataset
  data(ACL394filtered)

  #resetting all the filters
  X<-QC.reset(X)

  #filtering by fft.stat
  cplot(X,~fft.stat) #see what cut to use
  X<-QC.filter(X,fft.stat < 0.5) #apply the cut

  #filtering by the total number of frames in which a cell appears
  cplot(X,cellID~t.frame,fill=f.tot.y,geom="tile",facets=~pos)
  X<-update_n.tot(X) #updating n.tot variable
  cplot(X,~n.tot) #define where to apply the cut
  X<-QC.filter(X,n.tot==14) #keep cells that appear in all t.frames

  #exclude cells by ucid (Unique Cell ID)
  cplot(X,f.total.y~time.min,facets=~AF.nM,size=0.3,geom="jitter")
  #selecting cells that dont respond
  c1=select.cells(X,f.total.y<10e4&t.frame>3,n.tot.subset=n.tot>=8)
  X<-QC.filter(X,!ucid %in% c1)

  #undoing the last filter
  X<-QC.undo(X)

}

```

`read.cell.image`*Reads a Cell Image*

Description

Reads a cell image object from disk.

Usage`read.cell.image(file,...)`**Arguments**

| | |
|-------------------|----------------------------------------------------|
| <code>file</code> | filename or filename with path to the saved image |
| <code>...</code> | further arguments passed to <code>readImage</code> |

Details

This function is a wrapper over `readImage`. It reads a image saved by `write.cell.image`, with the image description database.

Author(s)

Alan Bush

See Also

`readImage`

Examples

```
## Not run:
#load example dataset

data(ACL394filtered)

ci<-get.cell.image(X,subset=match(pos,c(1,8,15,22,29),nomatch=0)>0&t.frame==11,
  group=(pos),N=3,channel=c(BF.out,YFP))

write.cell.image(ci,"Example-cell-image.tif")

ci2<-read.cell.image("Example-cell-image.tif")

## End(Not run)
```

remove.vars

Remove Variables from a Cell Data Object

Description

Returns a `cell.data` object, with the specified variables removed

Usage

```
remove.vars(X,select,exclude=NULL)
```

Arguments

| | |
|----------------------|------------------------------------------------------------------------------------------------------------------------------|
| <code>X</code> | cell.data object |
| <code>select</code> | character vector defining variables names to be removed in the returned <code>cell.data</code> |
| <code>exclude</code> | character vector defining variable names to be kept (not removed). This argument is somewhat counterintuitive (see details). |

Details

It defines variables to be excluded from the selected ones to be removed.

`remove.vars` is used to eliminate variables one is not interested in. This significantly reduces the size of the `cell.data` object and therefore the size of the working environment when saved (to a `.RData`). It also reduced the chance of memory issues. In the call to `remove.vars` `select` defines which variables are to be removed. You can use wildchars. For example to remove all nuclear variables use `select="*nucl*`. The `exclude` argument defines variables to be excluded from the selected ones to be deleted. For example if you want to remove all nuclear vars, except `f.nucl.y` use `select="*nucl*", exclude="f.nucl.y"`.

Value

a `cell.data` object with the specified variables removed

Author(s)

Alan Bush

See Also

[subset](#), [summary.cell.data](#)

Examples

```
if(require(RcellData)){  
  
  #load example dataset  
  data(ACL394)  
  
  #remove a variable  
  X<-remove.vars(X,select="f.vacuole.y")  
  
  #remove all background variables  
  X<-remove.vars(X,select="*bg*")  
  
  #remove all nuclear variables, except for f.nucl.y  
  X<-remove.vars(X,select="*nucl*",exclude="f.nucl.y")  
  
  summary(X)  
}
```

Description

Reshapes the data in a `cell.data` object and returns a `data.frame`

Usage

```
reshape(data,...)

## S3 method for class cell.data
reshape(data,formula = pos + cellID ~ variable + t.frame
,fun.aggregate=NULL, ..., margins=FALSE, fill=NULL
,id.vars=NULL, measure.vars=NULL, variable_name = "variable", na.rm = FALSE
,subset=TRUE ,select=NULL ,exclude=NULL ,QC.filter=TRUE)
```

Arguments

| | |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code> | cell.data object |
| <code>formula</code> | casting formula, see details for specifics |
| <code>fun.aggregate</code> | aggregation function |
| <code>...</code> | further arguments are passed to aggregating function |
| <code>margins</code> | vector of variable names (can include 'grand_col' and 'grand_row') to compute margins for, or TRUE to computer all margins |
| <code>fill</code> | value with which to fill in structural missing, defaults to value from applying <code>fun.aggregate</code> to 0 length vector |
| <code>id.vars</code> | character vector of id variables names, wildcard pattern or keyword. If NULL, will use all variables of the formula. |
| <code>measure.vars</code> | character vector of measure variables names, wildcard pattern or keyword. If NULL, will use all non id.vars variables. |
| <code>variable_name</code> | Name of the variable that will store the names of the original variables |
| <code>na.rm</code> | Should NA values be removed from the data set? |
| <code>subset</code> | a boolean vector of length equal to the number of rows of the dataset, or a conditional statement using the dataset's variable, that specifies which registers should be included |
| <code>select</code> | character vector defining variables names to be included in the returned data.frame |
| <code>exclude</code> | character vector defining variables names to be excluded from the returned data.frame |
| <code>QC.filter</code> | a boolean value indicating if the quality control filter should be applied over the data |

Details

This function is a wrapper over [melt](#) and [cast](#) from the reshape package of Hadley Wickham.

The id variables are selected by default. You can use [summary.cell.data](#) to see which variables are used as defaults for `id.vars`. The measured variables can be specified with `select` and `exclude`, or with `measure.vars`.

The casting formula has the following format: `x_variable + x_2 ~ y_variable + y_2 ~ z_variable ~ ... | 1:`
The order of the variables makes a difference. The first varies slowest, and the last fastest. There are a couple of special variables: `'...'` represents all other variables not used in the formula and `'.'` represents no variable, so you can do `formula=var1 ~ .`

If the combination of variables you supply does not uniquely identify one row in the original data set, you will need to supply an aggregating function, `fun.aggregate`. This function should take a vector of numbers and return a summary statistic(s). It must return the same number of arguments regardless of the length of the input vector. If it returns multiple value you can use

result_variable to control where they appear. By default they will appear as the last column variable.

The margins argument should be passed a vector of variable names, eg. c('pos','t.frame'). It will silently drop any variables that can not be margined over. You can also use 'grand_col' and 'grand_row' to get grand row and column margins respectively.

Value

a reshaped data.frame

Author(s)

Alan Bush

See Also

[aggregate](#)

Examples

```
if(require(RcellData)){
  #load example dataset
  data(ACL394)

  #rehape position 1 in pos + cellID ~ variable + t.frame for f.tot.y variable
  reshape(X,select="f.tot.y",subset=pos==1)

  #redefining the formula, reshape against time in minutes
  X<-transform(X,time.min=10+t.frame*15) #calculating the time of each t.frame
  reshape(X,pos+cellID~variable+time.min,select="f.tot.y",subset=pos==1&t.frame<10)
}
```

revFactor

Reverse Factor Levels

Description

Reverse the order of the levels of a factor

Usage

```
revFactor(x)
```

Arguments

x a factor

Details

Useful to use in calls to [cimage](#)

Value

a ordered factor with the levels in the reverse order of levels(x).

Author(s)

Alan Bush

Examples

```
#create a factor
f<-factor(paste0("f",1:9))
levels(f)

#reverse the order of the levels
rf<-revFactor(f)
levels(rf)
```

| | |
|--------------|-------------------------------|
| select.cells | <i>Select Subset of Cells</i> |
|--------------|-------------------------------|

Description

Selects a subset of cells that satisfy the specified conditions.

Usage

```
select.cells(X, subset = TRUE, n.tot.subset=NULL ,QC.filter=TRUE)
```

Arguments

| | |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X | cell.data object |
| subset | a boolean vector of length equal to the number of rows of the dataset, or a conditional statement using the dataset's variable, that specifies which registers should be included |
| n.tot.subset | a conditional statement usually involving n.tot, to filter the cells by the total number of frames in which they appear. |
| QC.filter | a boolean value indicating if the QC.filter should be applied over the data |

Details

select a group of cells by a criteria specified in subset. After the first subset is applied the number of frames in which a selected cell appears (n.tot) is calculated and an additional filter (n.tot.subset) is applied. This can be useful to select cells that satisfy the specified subset filter in all the time frames, or a fraction of them.

You can do union, intersection and difference of these sets.

Value

Returns a vector of the selected cells 'ucid'. The ucid (or 'unique cell id') is defined as pos*100000+cellID. Because the returned value is an integer vector all the set operations may be applied directly over subsets of cells selected by select.cells. The returned vector should be assigned to a variable for further usage.

Author(s)

Alan Bush

See Also[intersect](#), [union](#), [setdiff](#)**Examples**

```

if(require(RcellData)){

  #load example dataset
  data(ACL394)

  #select cells that have f.tot.y>1e7 in at least one t.frame
  c1<-select.cells(X,f.tot.y>1e7)
  cplot(X,f.tot.y~t.frame,color="gray",size=0.5) + #plotting the cells
  clayer(X,f.tot.y~t.frame,color=ucid,geom="line",subset=ucid%in%c1)

  #select cells that have f.tot.y<6e5 in all t.frames
  c1<-select.cells(X,f.tot.y<6e5,n.tot.subset=n.tot==14)
  cplot(X,f.tot.y~t.frame,color="gray",size=0.5) + #plotting the cells
  clayer(X,f.tot.y~t.frame,color=ucid,geom="line",subset=ucid%in%c1)
}

```

select.vars

*Select Variables***Description**

Selects a group of variable names from the dataset.

Usage

```
select.vars(X,select="all",exclude=NULL)
```

Arguments

| | |
|---------|-----------------------------------------------------------------------------------------------------------------|
| X | cell.data object |
| select | character vector defining variables names, keywords or wildcard patters to be included in the returned vector |
| exclude | character vector defining variables names, keywords or wildcard patters to be excluded from the returned vector |

Details

Selects a group of variables. If you only use the first argument it returns 'all' the columns of the dataset.

Value

A character vector with variable names.

Author(s)

Alan Bush

See Also[names](#)**Examples**

```
if(require(RcellData)){  
  
  #load example dataset  
  data(ACL394)  
  
  #select all variables  
  select.vars(X)  
  
  #select morphological variables  
  select.vars(X,"morpho")  
  
  #select variables of the YFP channel  
  select.vars(X,"*.y")  
  
  #select id vars, area vars and f.tot.y  
  select.vars(X,c("id.vars","a.*","f.tot.y"))  
  
  #select id vars, area vars and f.tot.y, exclude bg variables  
  select.vars(X,c("id.vars","a.*","f.tot.y"),exclude="*bg*")  
  
}
```

`show.img`*Show a Image*

Description

Display one or several BF or fluorescent images, indicating the cells eliminated by the QC filter.

Usage

```
show.img(X,pos,t.frame=0,channel="BF.out",image.title=""  
  ,annotate=NULL,cross=!QC,QC.filter=FALSE,subset=TRUE,cross.col=c(0.1,0.9)  
  ,display=interactive(),normalize=TRUE,...)
```

```
show.image(X,pos,t.frame=0,channel="BF.out",image.title=""  
  ,annotate=NULL,cross=!QC,QC.filter=FALSE,subset=TRUE,cross.col=c(0.1,0.9)  
  ,display=interactive(),normalize=TRUE,...)
```

Arguments

| | |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>X</code> | cell.data object as returned by load.cellID.data |
| <code>pos</code> | The position(s) of interest, from which the image will be shown. |
| <code>t.frame</code> | The time frame(s) of interest, from which the image will be shown. If it is a vector shorter than <code>pos</code> , it is recycled. |
| <code>channel</code> | the fluorescent channel label of interest. Usual values are 'BF', 'BF.out', 'YFP', 'YFP.out', etc. If it is shorter than <code>pos</code> or <code>t.frame</code> it is recycled. |
| <code>image.title</code> | optional title for the image |
| <code>annotate</code> | character vector with variable names with which to annotate the image. A usual value is 'cellID'. NOT IMPLEMENTED CURRENTLY! |
| <code>cross</code> | conditional statement with <code>X</code> variables indicating over which cells should a cross be placed. |
| <code>QC.filter</code> | boolean value, indicating if <code>X</code> should be subset by <code>QC.filter</code> before <code>cross</code> or <code>annotate</code> are applied. Default to FALSE. |
| <code>subset</code> | conditional statement using <code>X</code> variables used to subset <code>X</code> before other arguments are applied. |
| <code>cross.col</code> | vector of colors (gray levels) to be used for the crosses. Each mark is composed of two cross with the specified colors, moved one pixel from each other. Using a black and white enhances contrast. |
| <code>display</code> | boolean indicating if the created image should be displayed |
| <code>normalize</code> | boolean indicating if the images should be normalized to enhance contrast |
| <code>...</code> | further arguments |

Details

Displays the bright field and/or fluorescence images. Cells can be annotated with a cross or the value of a selected variable. This function can be used as a feedback to verify that the cuts used for [QC.filter](#) were adequate.

Value

It returns a [invisible](#) EBImage image.

Note

This function requires EBImage package installed which, in turn, requires the ImageMagick software.

Author(s)

Alan Bush

EBImage

Examples

```
if(interactive())&require(EBImage,quietly=TRUE)&require(RcellData)){
  #load example dataset
  data(ACL394filtered)

  #display the BF out image from position 8 and t.frame 11
  show.img(X,pos=8,t.frame=11)

  #display a stack of the YFP images of position 29
  show.img(X,pos=29,t.frame=7:11,channel="YFP")
}
```

 subset

Subset a Cell Data Objects

Description

Returns subset of the cell.data object which meet conditions

Usage

```
## S3 method for class cell.data
subset(x,subset=TRUE,select="all",exclude=NULL,QC.filter=FALSE,...)
```

Arguments

| | |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x | cell.data object |
| subset | a boolean vector of length equal to the number of rows of the dataset, or a conditional statement using the dataset's variable, that specifies which registers should be included |
| select | character vector defining variables names to be included in the returned cell.data |
| exclude | character vector defining variables names to be excluded from the returned cell.data |
| QC.filter | a boolean value indicating if the quality control filter should be applied over the data before creating the new cell.data object |
| ... | further arguments passed to or used by methods |

Details

`subset` is a generic function. This version applies to cell.data objects. `subset` is a close function, meaning it returns an object of the same class as its first argument, in this case a cell.data object. Subsetting is useful to divide a large experiment into smaller dataset that are more easily analyzed. It can also be used to reduce the memory space a cell.data object occupies, for example eliminating the QC filtered registers (`X<-subset(X,QC.filter=TRUE)`) or eliminating unused variables (`X<-subset(X,exclude=c("morpho","f.bg.y","f.*.c"))`)

The bracket (**Extract**) notation can also be used `Y<-X[pos==1]`

`remove.vars` is a wrapper over `subset`, it eliminates the specified variables.

A record of the subset history of the object is kept. Use `summary.cell.data` to see it.

Value

a subset cell.data object

Author(s)

Alan Bush

See Also

[subset](#), [summary.cell.data](#)

Examples

```
if(require(RcellData)){  
  
  #load example dataset  
  data(ACL394)  
  
  #subset the cell.data by pos  
  X1<-subset(X,pos==1)  
  X1<-X[pos==1]  
  
  #subset by t.frame and select variables  
  #note the use of keywords and pattern matching to select the variables  
  X.t13<-X[t.frame==13,c("morpho","*.y","f.tot.c")]  
  summary(X.t13) #take a look at the new cell.data object  
  
  #eliminate registers that didnt pass the QC filter  
  X<-subset(X,QC.filter=TRUE)  
  
}
```

summary

Cell Data Object Summary

Description

Returns a summary of the cell.data object content.

Usage

```
## S3 method for class cell.data  
summary(object,...)
```

Arguments

| | |
|--------|------------------------------------------------|
| object | cell.data object |
| ... | further arguments passed to or used by methods |

Details

Returns a description of the `cell.data` object, including from where and when it was loaded, the number of positions and time frames and information about the default, transformed and merged variables. It also returns a history of the QC filters and subsets applied.

The function returns a list of class `summary.cell.data` that is printed by `print.summary.cell.data`.

Value

a list of class `summary.cell.data`

Author(s)

Alan Bush

See Also

[summary](#)

Examples

```
if(require(RcellData)){  
  
  #load example dataset  
  data(ACL394)  
  
  #see the object summary  
  summary(X)  
  
  #assign the object summary  
  X.sum<-summary(X)  
  names(X.sum)  
  
}
```

transform

Transform a Cell Data Object

Description

Transforms a `cell.data` object adding new variables

Usage

```
## S3 method for class cell.data  
transform(_data,...,QC.filter=TRUE)  
  
transformBy(_data,.by,...)  
  
## S3 method for class cell.data  
transformBy(_data,.by,...,QC.filter=TRUE)
```

```
## S3 method for class data.frame
transformBy(_data, .by, ..., subset=NULL)

## Default S3 method:
transformBy(_data, .by, ..., subset=NULL)
```

Arguments

| | |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_data</code> | cell.data object or data.frame to transform |
| <code>.by</code> | variables to split data frame by, as quoted variable |
| <code>...</code> | new variable definition in the form tag=value |
| <code>QC.filter</code> | a boolean value indicating if the quality control filter should be applied over the data |
| <code>subset</code> | logical expression indicating elements or rows to keep: missing values are taken as false. Only valid for data.frames, not for cell.data |

Details

NOTE: `transform.by` had to be removed from the package. Use `transformBy` instead.

Read the `transform` vignette for a tutorial on the use of these functions
`> vignette("transform")`

`transform.cell.data` is the implementation of the generic function `transform` to `cell.data` objects. It creates the new variables based on the `...` argument; a tagged vector expressions, which are evaluated in the dataset.

`transformBy` is a generic function. Before transforming the dataset, the function splits it by the variables specified in the `.by` argument. This argument should be a quoted list of variables, that can be easily created with the `quoted` function, for example `.(pos, t.frame)`. This can be useful to do group-wise normalizations.

The transformed variables are summarized in the output of `summary.cell.data`.

Value

for `transform(By).cell.data` a transformed `cell.data` object
 for `transformBy.data.frame` a transformed `data.frame`

Author(s)

Alan Bush

See Also

[transform](#)

Examples

```
if(require(RcellData)){
  #load example dataset
  data(ACL394filtered)
```

```

#creating a new variable
X<-transform(X,f.total.y=f.tot.y-a.tot*f.local.bg.y)

#create a new variable normalizing by position
X<-transformBy(X,.(pos),norm.f.total.y=f.total.y/mean(f.total.y))

#create a new delta variable in sigle cells
X<-transformBy(X,.(pos,cellID),delta.f.total.y=f.total.y-f.total.y[t.frame==0])

#transformBy can also be used on a data.frame
df<-aggregate(X,f.total.y~t.frame+pos) #creates a aggregate data.frame from X
df<-transformBy(df,.(pos),delta.f.total.y=f.total.y-f.total.y[t.frame==0])

}

```

transform.cell.image.rd

Transform Cell Image

Description

funcionts that transforms a cell image object before plotting

Usage

```
cnormalize(X=NULL,normalize.group=c("channel"),ft=c(0,1),...)
```

```
ciciply(X=NULL,group=c("pos","cellID","channel"),FUN=sum,MARGIN=c(1,2),warn=TRUE)
```

```
add.nucleus.boundary(X=NULL,radii=c(2,3,4,5,6,7),pos.nucl.channel="YFP",col=0.75,...)
```

```
add.maj.min.axis(X=NULL,col=0.75,angle.var=NA,...)
```

Arguments

| | |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| X | cell.image object to transform |
| normalize.group | character vector indicating which variables should be used to group the images for normalization |
| ft | A numeric vector of 2 values, target minimum and maximum intensity values after normalization. |
| group | character vector indicating which variables should be used to group the images before applying FUN |
| FUN | function to apply to the grouped imaged matrix |
| MARGIN | a vector giving the subscripts which the function will be applied over. 1 indicates rows, 2 indicates columns, c(1, 2) indicates rows and columns. |
| warn | boolean indicating if warnings should be issued. |
| radii | radii of the concentric circles to be plot around the nucleus found position. The defaults correspond to Cell-ID default values |

| | |
|------------------|-----------------------------------------------------------------------------------------------------------------------------|
| pos.nucl.channel | string indicating channel from which the nucleus coordinates should be extracted |
| col | color to use for the nucleus boundary |
| angle.var | string indicating variable that measures the angle between the major axis and a horizontal line (not calculated by Cell-ID) |
| ... | further arguments for methods |

Details

All these functions take a `cell.image` object as their first argument, and return a modified `cell.image` object. In combination with `get.cell.image` and `cimage.cell.image` they can be used to do custom manipulation to the cell's images.

`cnormalize` is called from `cimage` to normalize the images before plotting. It normalizes the images to enhance contrast. The normalization groups (defined by `normalize.group`) are applied the same normalization, so the intensities can be compared within a group.

`cicply` is inspired on the `plyr` package. It divides the `cell.image` object into groups defined by the `group` argument, combines the images within a group in a stack (or array) and applies the `FUN` function, over the defined margins. For example if `FUN=sum` and `MARGIN=c(1,2)`, several images are add up together. This can be used to create Z-projections.

`add.nucleus.boundary` and `add.maj.min.axis` overlay the nucleus boundary and the major and minor axis respectively on the cell's images.

if `X` is `NULL`, the function returns a character indicating with variables of the dataset it requires.

Value

The transformed `cell.image` object

Author(s)

Alan Bush

}

```

| | |
|-----------------|--------------------------|
| update_img.path | <i>Update Image Path</i> |
|-----------------|--------------------------|

Description

Updates the path to the images folder. Useful if the images are in a different location from the one they were run by Cell-ID.

Usage

```
update_img.path(X, img.path=getwd(), subset=NULL)
```

Arguments

| | |
|----------|------------------------------------------------------------------|
| X | cell.data object |
| img.path | character with the new path to the images |
| subset | conditional expression to update the paths of a subset of images |

Value

returns a cell.data object, with updated paths for the images

Author(s)

Alan Bush

|--------------|-------------------------------------------------------|
| update_n.tot | <i>Calculate Total Number of Frames for Each Cell</i> |
|--------------|-------------------------------------------------------|

Description

updates n.tot, the total amounts of frames in which a given cell appears

Usage

```
update_n.tot(object, QC.filter = TRUE, ...)
```

Arguments

| | |
|-----------|----------------------------------------------------------------------------|
| object | cell.data object |
| QC.filter | a boolean value indicating if the quality control filter should be applied |
| ... | further arguments for methods |

Value

returns a cell.data object, with updated values for n.tot

Author(s)

Alan Bush

  data(ACL394)
  grid.newpage() #create a new plot
  pushViewport(viewport(layout = grid.layout(1, 2))) #define the grid for the plots
  print(cplot(X,f.tot.y~pos), vp = vplayout(1, 1))
  print(cplot(X,f.tot.y~a.tot,color=pos), vp = vplayout(1, 2))
}
```

with

Evaluates an Expression in a Cell Data Object.

Description

Evaluate an R expression in an environment constructed from the cell.data object.

Usage

```
## S3 method for class cell.data
with(data,expr,subset=TRUE,select=NULL,exclude=NULL,QC.filter=TRUE,...)
```

Arguments

| | |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data | cell.data object |
| expr | expression to evaluate |
| ... | arguments to be passed to future methods |
| subset | a boolean vector of length equal to the number of rows of the dataset, or a conditional statement using the dataset's variable, that specifies which registers should be included |
| select | character vector defining variables names to be included |
| exclude | character vector defining variables names to be excluded |
| QC.filter | a boolean value indicating if the quality control filter should be applied over the data |

Details

`with` is a generic function. The version for `cell.data` objects is a wrapper over the version for `data.frame`, calling `as.data.frame.cell.data` with the specified arguments.

Value

The value of the evaluated `expr`

Author(s)

Alan Bush

[with](#)

Examples

```
if(require(RcellData)){  
  
  #load example dataset  
  data(ACL394)  
  
  #calculate the mean f.tot.y from pos 2  
  with(X,mean(f.tot.y[pos==2]))  
  
  #use base plotting  
  with(X,plot(f.tot.y~f.tot.c))  
  
}
```

write.cell.image *Write a Cell Image*

Description

Writes a cell image object to disk.

Usage

```
write.cell.image(x, file = "",...)
```

Arguments

| | |
|------|-------------------------------------------------------------------|
| x | the cell.image object, as returned by get.cell.image, to be saved |
| file | filename or filename with path to save the image |
| ... | further arguments passed to writeImage |

Details

This function is a wrapper over writeImage. It combines images of the cell.image object in a stack, saves it to disk, and saves the image description database as a tab delimited file, with the name given in file argument.

Author(s)

Alan Bush

See Also

writeImage

Examples

```
## Not run:
#load example dataset
library(RcellData)
data(ACL394filtered)

#select N=3 cells images from each pos (group),
#from the first t.frame and pos 1,8,15,22,29.
ci<-get.cell.image(X,subset=match(pos,c(1,8,15,22,29),nomatch=0)>0&t.frame==11,
  group=.(pos),N=3,channel=c(BF.out,YFP))

write.cell.image(ci,"Example-cell-image.tif")

## End(Not run)
```

| | |
|-------------|--------------------|
| write.delim | <i>Data output</i> |
|-------------|--------------------|

Description

Writes a Tab Delimited Table text table to disk.

Usage

```
write.delim(x, file = "", quote = FALSE, sep = "\t", row.names = FALSE,...)
```

Arguments

| | |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x | the object to be written, preferably a matrix or data frame. If not, it is attempted to coerce x to a data frame. |
| file | either a character string naming a file or a connection open for writing. "" indicates output to the console. |
| quote | a logical value (TRUE or FALSE) or a numeric vector. If TRUE, any character or factor columns will be surrounded by double quotes. If a numeric vector, its elements are taken as the indices of columns to quote. In both cases, row and column names are quoted if they are written. If FALSE, nothing is quoted. |
| sep | the field separator string. Values within each row of x are separated by this string. |
| row.names | either a logical value indicating whether the row names of x are to be written along with x, or a character vector of row names to be written. |
| ... | further arguments passed to write.table |

Details

This function is a wrapper over write.table with defaults to write a nice tab delimited text file.

Author(s)

Alan Bush

See Also

[write.table](#)

Examples

```
if(require(RcellData)){
  data(ACL394)
  agg<-aggregateBy(X,.(pos),select="f.tot.y",subset=t.frame==0,FUN=mean)
  if(interactive()) write.delim(agg,"myTable.txt")
}
```

zoom

*Zoom in a ggplot Object***Description**

Sets the plotting region and axes breaks for a ggplot object

Usage

```
zoom(xzoom=c(NA, NA), yzoom=c(NA, NA), expand.y=c(0, 0), expand.x=c(0, 0), nx.breaks=n.breaks,
     ny.breaks=n.breaks, n.breaks=7, ...)
caxis(xzoom=c(NA, NA), yzoom=c(NA, NA), expand.y=c(0, 0), expand.x=c(0, 0), nx.breaks=n.breaks,
      ny.breaks=n.breaks, n.breaks=7, ...)
xzoom(xzoom=c(NA, NA), nx.breaks=7, ...)
yzoom(yzoom=c(NA, NA), ny.breaks=7, ...)
```

Arguments

| | |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| xzoom | numeric vector. If length=2 it specifies the range of the x axis, if length>2 it gives the braks to be used. |
| yzoom | numeric vector. If length=2 it specifies the range of the x axis, if length>2 it gives the braks to be used. |
| expand.x | numeric vector of length two, with x axis additive expansion. Note the first element is usually negative. This expansion does not modify the position of the ticks. |
| expand.y | idem for y axis |
| nx.breaks | number of breaks for the x axis |
| ny.breaks | number of breaks for the y axis |
| n.breaks | number of breaks for both axes, if not specified by nx.breaks or ny.breaks |
| ... | further arguments for pretty or scale_continuous |

Details

xzoom and yzoom are convenient functions to specify only one of the limits.

Value

a layer to be added to a ggplot object, that specifies the plotting region after the statistical transformations have been done.

Note

A zoom function exists in Hmisc package. Use `Rcell::zoom` or `caxis` if both package namespaces are loaded.

Author(s)

Alan Bush

See Also[cplot,limits](#)**Examples**

```
if(require(RcellData)){  
  
  #load example dataset  
  data(ACL394)  
  
  #zoom in the y axis  
  cplotmeans(X,f.tot.y~t.frame,color=pos) + zoom(y=c(0,7e6))  
  
  #define plotting region and ticks  
  cplotmeans(X,f.tot.y~t.frame,color=pos) + caxis(y=c(0,7e6),x=c(0,13),nx=14,expand.x=c(-.75,.75))  
}
